Nature

A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

VOLUME LXV

NOVEMBER 1901 to APRIL 1902

*"To the solid ground
Of Nature trusts the mind which builds for aye."*—WORDSWORTH.

London
MACMILLAN AND CO., LIMITED
NEW YORK: THE MACMILLAN COMPANY

RICHARD CLAY AND SONS, LIMITED,
LONDON AND BUNGAY.

INDEX.

ABEGG, Practical Chemistry, 410
Abel (Dr. O.), Curiously Marked Pebbles from the Algerian Sahara, 594
Academy, the Proposed British, 418
Academy, the Royal Society and the Proposed, 393
Acarology: British Tyroglyphidæ, Albert D. Michael, 482
Accumulators for Electric Automobiles, Progress in the Design of, Sir H. P. Maxim, 572
Acetic Acid, the Molecular Complexity of, in Chloroform Solution, H. M. Dawson, 527
Acetone, on the Electrolytic Preparation of the Halogen Derivatives of, A. Richard, 119
Acetylene, the Dilution of Acetylene for Heating Purposes, A. E. Munby, 30; Determination of the Heat of Dissociation and Combustion of, W. G. Mixter, 93; Report of the Committee on Acetylene Generators, 472; Synthesis of Acetylenic Acetones and β-Ketonic Ethers, Ch. Moureu and R. Delange, 263
Achariach, New Meteorological Station at, 85
"Acker" Fusion Process for the Electrolytic Production of Caustic Alkali and Chlorine at Niagara Falls, 324
Acheson Graphite Company (Niagara Falls), Electrodes Manufactured by the, 420
Actions, Automatic, Will. A. Dixon, 102; Dr. W. Benthall, 152
Acoustics, Location of Open-Air Sound Loops and Nodes. Bergen Davis, 22; the Value of the Horns in Bighorn Wild Sheep as Ear-trumpets, George Wherry, 127; Change of Pitch in certain Sounds with Distance, Frederick M. West, 129; Dr. D. van Gulik, 174; Paul R. Heyl, 273; R. Freeman, 317; Air-Pressures in Playing Brass Instruments, Dr. E. H. Barton and S. C. Laws, 166; Experimental Phonetics, Prof. G. McKendrick, F.R.S., 182; the Interference of Sound, Lord Rayleigh, F.R.S., 278; Miniature Anemometer for Stationary Sound Waves, B. Davis, 404; Sounds Associated with Low Temperatures, Sir W. H. Preece, F.R.S., 487; Prof. J. D. Everett, F.R.S., 512; Charles J. P. Cave, 512; Spencer Pickering. F.R.S., 536
Adams (John Couch, F.R.S.). Lectures on the Lunar Theory, 583
Advanced Exercises in Practical Physics, Prof. Arthur Schuster and Dr. C. H. Lees, 364
Aeronautics: the Meteorological Observations of the International Balloon Ascents of November 8, 1900, Dr. Hergesell, 36; International Balloon Ascents of June 13, 110; Meteorological Results of International Balloon Ascents, 229; International Balloon Ascents, December 5, 302; International Balloon Ascents on January 9, 421; Herr Kress's Machine, 87; Aërial Navigation by Bodies Heavier than Air, William Marriott and Eric Stuart Bruce, 167; Aëronautical Society, 167; Kites and Wireless Telegraphy, Dr. A. Lawrence Rotch, 198: Scientific Ballooning, W. N. Shaw, F.R.S., 224; the Determination of the exact Trajectory of Aërostats with Respect to the Soil, H. Deslandres, 383; the Wreck of *Santos Dumont* No. 6, Dr. J. Y. Buchanan, F.R.S., 397; Novel Form of Flying Machine, Henri Villard, 518; Aëronautical Experiments with Gliding Machines, Wilbur Wright, 541
Aëroplane Machine, Herr Kress's, 87
Æther, Drift of the, the FitzGerald Lorentz Effect, Prof. W. M. Hicks, F.R.S., 343
Africa: the Sierra Leone Campaign against Mosquitoes, Major Ronald Ross, 35; Mr. Jonathan Hutchinson's Expedition to Study Leprosy in South Africa, 109; Primary Cause of Leprosy, J. Hutchinson, F.R.S., 496; on the Earwigs, Cockroaches, Mantids and Stick-Insects Collected by Dr. Donaldson Smith in North-East Africa, J. A. G. Rehn, 180; the Extinct Blaauwbok of South Africa, G. Renshaw, 207; Mosasaurus, &c., Bones from Natal Coast Cretaceous, 229; the Birds of South Africa, A. C. Stark, completed by W. L. Sclater, 244; Peculiar Case of Fever with Parasite resembling that of Tsetse Fly Disease, Dr. J. Everett Dutton, 255; to the Mountains of the Moon, J. E. S. Moore, 273; Marine Organism from South Africa, 287; Death and Obituary Notice of Dr. Emil Holub, 396; the Native Question in South Africa, 440; the Obstacles to Development in West Africa, Dr. C. F. Harford-Battersby, 371; Note on the Discovery of a New Trypanosoma, Lieut.-Colonel D. Bruce, F.R.S., 454; Composition of an Antique Vase, M. Berthelot, 455; Petrology of British East Africa, G. T. Prior, 549; Prehistoric Graves and Remains at Girga, Egypt, to be Investigated by Dr. Elliott Smith, 571; Curiously Marked Pebbles from the Algerian Sahara, Dr. O. Abel, 594
Agassiz (Prof. A.), Exploration of the Maldives, 398
Agazzetti (A.), Attempt to Train Flight of Pigeon whose Cerebral Hemisphere has been removed, 65
Agriculture; Sugar Cane Experiments in Antigua and St. Kitts, Francis Watts, 36; Sugar Canes at Barbadoes, Prof. D'Albuquerque and Mr. Bovell, 231; Experimental Cultivation of Hops at Wye, 109; Prevention of "Smut" in Oats, Prof. T. Johnson, 142; Damage done by "Smut" to the Irish Oat Crop, and the Use of an American fungicide, "Sar," Prof. Johnson, 518; Death and Obituary Notice of Sir J. Henry Gilbert, LL.D., F.R.S., 205; Cultivation of Clover on Soils Deprived of Lime, P. P. Dehérain and E. Demoussy, 215; Cultivation of Lucerne upon Soils without Lime, P. Dehérain and E. Demoussy, 287; the Small Farm and its Management, James Long, 271; Chemical Modifications in Plants submitted to the Influence of Sodium Chloride, E. Charabot and E. Hébert, 312; the West Indian Agricultural Conference, 1902, Prof. J. P. d'Albuquerque, 331; the Journal of the Royal Agricultural Society of England, 483; Culture of Fodder Beet, P. P. Dehérain, 504; Susceptibility of Different Species of Bromegrasses to the Attacks of the Rust Fungus, Prof. Marshall Ward, F.R.S., 519; Poultry Management on a Farm, Walter Palmer, 583: the Uses of Electricity in Stimulating the Growth of Plants, Dr. Selim Lemström, 593
Air: on the Exploration of the Air at Sea by means of Kites, A. Lawrence Rotch, 118; the Cooling Power and Conductivity of Air, P. Compan, 215; Optical Effect produced by Refraction of Air, J. Barclay, 497; E. Edser, 497; Rotation of a Lamina Falling in Air, A. Mallock, 510; the Photography of Disturbances in Air, H. S. Allen, 574
Air-pressures in Playing Brass Instruments, Dr. E. H. Barton and S. C. Laws, 166
Airy's (Sir G.) Reflex Zenith Tube, Prof. S. C. Chandler, 214
Aitken (R. G.), Observations of 194 Double Stars, 400
Alaska, Western, Measles in, Dr. Moore, 86
Albertine (Prof.), Absorption of Sugar from Stomach and Intestine, 63
Albumins, Chemistry of the, 90
Algebra: College Algebra, Dr. J. H. Boyd, 338; Algebraical Examples, H. S. Hall, 343; the Theory of Equations, with an Introduction to the Theory of Binary Algebraic Forms, W. S. Burnside and A. W. Panton, 390
Algol, the Period of, 15
Algol Stars, Early Observations of, 325
Alia or Double Canoe, Polynesians', Prof. Thilenius, 256

Allchin (W. H., F.R.S.), a Manual of Medicine, 99
Allen (H. S.), the Red (C) Line of Hydrogen and the Zeeman Effect, 79; the Photography of Disturbances in Air, 574
Alloys of Aluminium and Magnesium, O. Boudouard, 167
Alloys of Copper and Tin, Microscopical Examination of, W. Campbell, 354
Alternating Currents, an Elementary Treatise on, W. G. Rhodes, 463
Amaryllideæ, Bulbiform Seeds of, Dr. A. B. Rendle, 38
Amazonenströmes, Die Vogelwelt des, Emil A. Goeldi, 173
America: Bulletin of the American Mathematical Society, 22, 140, 357, 546, 600; American Journal of Science, 22, 93, 190, 263, 404, 526, 599; the Great Deserts and Forests of North America, Paul Fountain, 57; Municipal Sanitation in the United States, Charles V. Chapin, 73; Notes on Axolotls from Colorado and Dakota, H. L. Osborne, 111; the Nesting and other Habits of one of the American Cat Fishes of the genus Amiurus, A. C. Eycleshymer, 111; Transactions of the American Mathematical Society, 117, 357; Marconi's Signalling from England to America by Wireless Telegraphy, 158; the Mammals of North America, 232; American Journal of Anatomy, 236; American Journal of Mathematics, 428; Central and South America, A. H. Keane, Col. George Earl Church, 512; the American Bison, 516; American Institute of Electrical Engineers, Committee's Report and Resolution in Favour of the Metric System, 540; Lord Kelvin in America, 591
Amphioxus, the Renal Organs of the, E. S. Goodrich, 541
Amundsen (Capt. R.), Proposed Exploring Expedition to the Magnetic North Pole, 497
Anastomosis, on Return of Voluntary Movements after Alteration of the Nerve-supply by Nerve-crossing or, Dr. R. Kennedy, 115
Anatomy: Die Medulla Oblongata und die Vierhügelgegend von Ornithorhynchus und Echidna, A. Koelliker, 1; an Atlas of the Medulla and Midbrain, Florence R. Sabin, 172; the Significance of Certain Features and Types of the External Ear, Dr. Arthur Keith, 16; Contributions to the Comparative Anatomy of the Mammaliam Eye, chiefly based on Ophthalmoscopic Examination, Dr. George Lindsay Johnson, 137; American Journal of Anatomy, 236; Normal Histology of Human Hæmolymph Glands, Dr. A. S. Worthin, 237; Morphology of Pineal Region, Prof. C. S. Minot, 237; Erlebtes und Erstrebtes, Carl Gegenbaur, 316; Der Gang des Menschen, Ueber die Bewegung des Fusses und die auf denselben einwirkenden Kräfte, Otto Fischer, 411; Ueber die Bewegung in den Handgelenken, Rudolf Fick, 411; Contributions to Anatomical Journals, Prof. Alex. Macalister, F.R.S., 416; the Writer of the Review, 416; Varieties of Forms of the Liver of the Primates, G. Ruge, 519; Morphological Importance of the Foramen Found at the lower end of the Humerus of many Mammals, and also of the Trochanter of the Femur, Dr. E. Stromer, 519
Ancient Model of a Boat and Warrior Crew Found at Roos, in Holderness, Thomas Sheppard, 256
Anderson (Mr.), on the Union of Hydrogen and Chlorine, 383
Anderson (Rev. Thos. D.), Award of the Jackson-Gwilt Medal of the Royal Astronomical Society to, 348
Andes de Patagonie, L. Gallois, Supp. November 14, 1901, ix
André (G.), Action of Temperature on the Mineral Absorption in Etiolated Plants, 504
Andrews (Thomas, F.R.S.), Micro-crystalline Structure of Platinum, 547
Anemometer, Miniature, for Stationary Sound Waves, B. Davis, 404
Animal Behaviour, C. Lloyd Morgan, F.R.S., 49
Animal Engravings of the Stone Age, a Gallery of, 299
Animal Photography, D. English, 33
Animals, Use-inheritance; Illustrated by the Direction of Hair on the Bodies of, W. Kidd, 4
Annals of Mathematics, 262, 357
Annular Eclipse of the Sun, November 10, 1901, the, 62; Annular Eclipse of the Sun, November 11, 1901, the, M. A. de la Baume Pluvinel, 215, 232
Anomalous Dispersion of Sodium Vapour, the, R. W. Wood, 284
Ant-rice, the so-called, Prof. W. M. Wheeler, 422
Antarctica: Arrival of *Discovery* at Lyttelton, 109; Departure of *Discovery* from Lyttelton for Dunedin, 178; the *Discovery* Expedition, 279; Voyage Southward of the *Discovery*, Sir Clements Markham, 592; to the South Polar Regions, Expedition of 1898–1900, Louis Bernacchi, 153; Purchase of the *Hecla* for William Bruce's forthcoming Expedition, 178; Departure of the *Antarctic* with Prof. Nordenskjöld's Expedition from Buenos Ayres, 178; Scottish Antarctic Expedition, 207; Scientific Work of the German Antarctic Expedition, Prof. Dr. Drygalski, 378
Anthropology: North Queensland Ethnography, Dr. Walter E. Roth, 9; the Nayars of Malabar, F. Fawcett, 37; the Play of Man, Karl Groos, 78; Anthropological Institute, 119; Brain of an Eskimo Man, Dr. A. Hrdlicka, 256; Fire Worship in Arizona, Dr. J. Walter Fewkes, 256; the Scope of Criminal Anthropology, 279; Rock-holes used by Aborigines for Warming Water, R. H. Mathews, 336; Textile Markings on Primitive Pottery, W. H. Holmes, 350; Folk-lore of the North American Indians from the Jesuit Relations (1611 to 1637), J. E. King, 406; Funeral Rites of the North American Indians, J. E. King, 527; Tattooing of Women in the Laughlan Islands, Prof. G. Thilenius, 445; Fire-making of the Yánádis, T. R. Rao, 473; the Mystic Rose: a Study of Primitive Marriage, Ernest Crawley, E. Sidney Hartland, 553; Prehistoric Graves and Remains at Girga, Egypt, to be investigated by Dr. Elliot Smith, 571; Head-hunters, Black, White, and Brown, Alfred C. Haddon, F.R.S., E. Sidney Hartland, Supp. April 24, 1902, iii.
Anthropometry: on the Relation between Intelligence and the Size and Shape of the Head, Paper Read before the Royal Society by Prof. Pearson, 543
Antigua Botanic Station, Summary of the Work at, for the Year ending March 31, 1901, W. N. Sands, 208
Antimony, Action of Lithium-ammonium on, and on the Properties of the Antimonide of Lithium, P. Lebeau, 359
Antlers, Evolution of Horns and, Dr. H. Gadow, F.R.S., 549
Apes: Physiology of Motor Area in Anthropoid Apes, A. S. F. Grunbaum and Prof. C. S. Sherrington, F.R.S., 65; Physiology of the Cerebral Cortex of Higher Apes, A. S. F. Grunbaum and Prof. C. S. Sherrington, F.R.S., 165
Aquarium, Exhibition of Electrical Appliances at the Royal 158
Arber (E. H. N.), Clarke Collection of New South Wales Fossil Plants, 94
Archæology: the Influence of the Mediterranean Peoples in Prehistoric Britain, Address at Vesey Club by Prof. Boyd Dawkins, F.R.S., 39; an attempt to ascertain the Date of the Original Construction of Stonehenge from its Orientation, Sir Norman Lockyer, K.C.B., F.R.S., and F. C. Penrose, F.R.S., 55; C. T. Whitmell, 128; Berthelot and the Metals of Antiquity, Dr. J. H. Gladstone, F.R.S., 82; Kharga Oasis, its Topography and Geology, J. Ball, 130; the Civilisation of Hallstatt and La Tene, Mittheilungen der Prähistorischen Commission der K. Academie der Wissenschaften in Wien, Dr. Robert Munro, 212; Discoveries in La Plata Island, Ecuador, Dr. G. A. Dorsey, 231; Ancient Model of a Boat and Warrior Crew found at Roos, in Holderness, Thomas Sheppard, 256; Fundamental Principles of the Old and New World Civilisations, vol. ii. of the Archæological and Ethnological Papers of the Peabody Museum, Zelia Nuttall, 268; a Gallery of Animal Engravings of the Stone Age, 299; Human Bone Instruments, R. Quick, 350; Pigmy Flints from Lincolnshire, Rev. R. A. Gatty, 372; Mycenæan Tree and Pillar Cult and its Mediterranean Relations, Arthur J. Evans, Supp. November 14, 1901, vi.
Architecture: Publications of the British Fire Prevention Committee, 169
Arctica: News from Baron Toll's Expedition, 228; the Kolymsk Mammoth, 228; the Musk-ox, 322; Proposed Exploring Expedition to the Magnetic North Pole, Captain R. Amundsen, 497
Argon, Classification of the Atomic Weights of Neon, Krypton, Xenon and, H. Wilde, 579–80
Aristotelian Society, Proceedings of the, 78
Arithmetic, R. Hargreaves, 29
Arizona, Fire-worship in, Dr. J. Walter Fewkes, 256
Armagnat (H.), Instruments et Méthodes de Mesures Electriques Industrielles, 342
"Armorl" Electric Capillary Relay, the, 129
Arms, does Man use His, in Locomotion? Basil W. Martin, 80; C. O. Bartrum, 102; Captain Giles A. Daubeny, 127
Arnaud (M.), Composition of the Amidotauric Acids, 604

Arrhenius' (Prof.) Theory of Cometary Tails and Auroræ, on, Dr. J. Halm, 415
d'Arsonval (M.), Production and Maintenance of Low Temperatures, 167; on the Action of High-frequency Currents upon Animals, 239
Artesian Waters of Australia, the, J. P. Thomson, 111; the Climate and Artesian Waters of Australia, J. P. Thomson, 350
Ash Constituents of some Lakeland Leaves, the, Dr. P. Q. Keegan, 80
Ashworth (J. Reginald), Results of some Recent Researches on the Properties of Various Electrical Rays, 180; Experiments on Drawn Steel, Part i. Magnetism and its Changes with Temperature, Part ii. Resistivity, Elasticity and Density, and the Temperature Coefficients of Resistivity and Elasticity, 526
Assyrian Language: Easy Lessons in the Cuneiform Inscriptions, L. W. King, 170
Assyrian, on Traces of an Indefinite Article in, R. Campbell Thompson, 412
Asteroid-orbit of Great Eccentricity, an, 161
Astronomy: the Tercentenary of Tycho Brahe's Death, Dr. J. L. E. Dreyer, Prof. Bohuslav, 5; Tycho Brahe's Observatory, Dr. J. L. E. Dreyer, 104; Tycho Brahe in Prague, Bericht über die astrologischen Studien des Reformators der beobachtenden Astronomie Tycho Brahe, F. J. Studnička, 181; Bericht über die Untersuchungen der Gebeine Tycho Brahe's, Dr. H. Matiegka, 181; the Period of Algol, 15; Variable Stars of Algol Type, Dr. A. W. Roberts, 94; Early Observations of Algol Stars, 325; the Melbourne Observatory, 15; Royal Alfred Observatory, Mauritius, 15; Our Astronomical Column, 15, 38, 62, 89, 112, 137, 161, 210, 232, 258, 282, 305, 325, 351, 374, 400, 423, 446, 475, 499, 520, 543, 574, 595; the Total Solar Eclipse of September 9, 1904, Dr. A. M. W. Downing, F.R.S., 30; the Annular Eclipse of the Sun, November 10, 1901, 62; the Annular Eclipse of the Sun, November 11, 1901, M. A. de la Baume Pluvinel, 232; Observations in Lower Egypt of the Annular Eclipse of the Sun of November 11, 1901, A. de la Baume-Pluvinel, 215; the Total Solar Eclipse, May 18, 1901, 210, 283; Magnetic Observations during Total Solar Eclipse, 210; Results of International Magnetic Observations made during the Total Solar Eclipse of May 17–18, 1901, Dr. L. A. Bauer, 246; Magnetic Observations during Total Solar Eclipse of May 18, 1901, Dr. W. van Bemmelen, 305; Planetary Influence on Sun-spot Period, 39; a New Solar Theory, Dr. J. Halm, 351; the Effective Temperature of the Sun, Dr. W. E. Wilson, F.R.S., 428; Distortion of Sun's Disc at Horizon, Prof. W. Prinz, 520; Simultaneous Visibility of Sun and Total Lunar Eclipse, Dr. C. Hillebrand, 305; Total Eclipse of the Moon on April 22, 574; Lectures on the Lunar Theory, John Couch Adams, F.R.S., 583; the Leonid Meteors, 38; the Leonid Meteors, November 1901, 62, 89; Observations of Leonid Meteors, E. C. Willis, 54; Leonid Observations at Athens, M. D. Eginitis, 143; the Leonid Shower of 1901, W. F. Denning, 332; Nebulosity surrounding Nova Persei, 38, 475; Structure of the Region around Nova Persei, 62; Proper Motion of Nova Persei, 62; the New Star in Perseus, Sir Norman Lockyer, K.C.B., F.R.S., 112; the Photographs of Nova Persei, Sir Norman Lockyer, K.C.B., F.R.S., 133; the Distance of Nova Persei, W. E. Wilson, F.R.S., 198, 298; Stars near Nova Persei, 210; Mean Parallax of Stars, 39; Distribution of Cosmic Velocities, 39; an Attempt to Ascertain the Date of the Original Construction of Stonehenge from its Orientation, Sir Norman Lockyer, K.C.B., F.R.S., and F. C. Penrose, F.R.S., 55; C. T. Whitmell, 128; New Variable Stars, 62, 137, 574; A. W. Roberts, 62; Variable Star Catalogue, 258; New Variable Star, 3, 1902 (Monocerotis), Prof. W. Ceraski, 475; Determination of Orbital Elements, F. C. Moulton, 63; Royal Astronomical Society, 71, 286, 405, 502, 602; Presentation of the Royal Astronomical Society's Gold Medal to Prof. J. C. Kapteyn, 348; Award of the Jackson-Gwilt Medal to Rev. Thos. D. Anderson, 348; Oeuvres complètes de Christiaan Huygens, 74; Astronomical Occurrences in December, 89; in January, 210; in February, 305; in March, 400; in April, 499; in May, 595; Motion of the Great Red Spot on Jupiter, 89; the Red Spot on Jupiter, A. Stanley Williams, 596; Diameter of Jupiter, 258; Observations of Jupiter, W. F. Denning, 446; Preliminary Investigation of the Diameter of Mars, 90; Definitive Orbit Elements of Comet 1899 I, 90; the Perseids of 1901, M. Perrotin, 95; Observations of Perseids at Athens, D. Eginitis, 95; Variation of Latitude, Prof. S. C. Chandler, 113; Determination of the Elevation of Meteors, 113; Meridian Observations at Harvard College Observatory, A. Searle, 113; Length of the Terrestrial Day, R. S. Woodward, 113; Bright Meteor of December 4, 137; Bright Meteor of December 16, 161; Companion to the Observatory 1902, 137; on the Equilibrium of Stellar Atmospheres, Dr. Halm, 143; Spectra of Bright Southern Stars, Photographed with the 13-inch Boyden Telescope as a Part of the Henry Draper Memorial, Annie J. Cannon, A. Fowler, 155; an Asteroid-Orbit of Great Eccentricity, 161; Heights of Shooting Stars in August 1901, C. Flammarion, 167; on the Compound (so-called Stationary) Radiants of Shooting Stars, Th. Bredikhine, 381; the Quadrantid Meteors, John R. Henry, 198; the Quadrantid Meteors, 1902, John R. Henry, 272; the Quadrantid Meteors, T. W. Backhouse, 439; Natal Observatory Report for 1900, 210; Sir G. Airy's Reflex Zenith Tube, Prof. S. C. Chandler, 214; the New Planetoid, S. B. Gaythorpe, 223; the Equatorial of the New Calcutta Observatory, 229; the Farmers' Years, Sir Norman Lockyer, K.C.B., F.R.S., 248; the Heavens at a Glance, 1902, 258; Catalogue of 100 New Double Stars, 258; Observations of 900 Double and Multiple Stars, Prof. Doolittle, 400; Observations of 194 Double Stars, R. G. Aitken, 400; Death of Commissary-General G. D. Lardner, 278; Dimensions of the Planets and Satellites, 282; Harvard College Observatory Report, 1901, 282; Two Theorems Relating to the Periodic Solutions of the Differential Equations of Dynamics and Astronomy, E. T. Whittaker, 286; the Earth's Beginning, Sir Robert S. Ball, F.R.S., 294; Nautical Astronomy, J. H. Colvin, 296; Variability of the Satellites of Saturn, L. Rudaux, 305; Prof. T. J. J. See, 305; United States Naval Observatory Report, 326; Apparatus for Measuring the Variations of Small Zenithal Distances, G. Lippmann, 335; Pleasures of the Telescope, Garrett P. Serviss, 343; Disturbance of Corona in Neighbourhood of Prominences, Prof. C. D. Perrine, 351; the New Bruce Spectrograph for the Yerkes Refractor, 374; Conditions to be realised in the Execution of Negatives to obtain Homogeneity and the Maximum of Exactitude in the Determination of the Coordinates of Stellar Images, M. Lœwy, 407; on Prof. Arrhenius' Theory of Cometary Tails and Auroras, Dr. J. Halm, 415; the Spectrum of the Chromosphere, S. A. Mitchell, 423; Photographic Determination of Longitude, G. Lippmann, 423; New Annual Terms in the Variation of Latitude, Prof. H. Kimura, 446; Explanation of some Celestial Phenomena by means of the Hertzian Waves, Charles Nordmann, 455; Tafeln zur Theoretischen Astronomie, Julius Bauschinger, 463; Origin of Disturbance in Corona May 17–18, 1901, 499; Foucault's Pendulum, 499; the Felix Meteorite, G. P. Merrill, 543; the Radiant Point of the April Lyrids, W. F. Denning, 578; Comet 1902a (Brooks), 595; Nebulæ and their Velocities in the Line of Sight, Dr. J. Hartmann, 595; the Relative Number of Star Images Photographed in different parts of a Plate, Prof. Turner, 602; the Stars: a Study of the Universe, Simon Newcomb, Prof. R. A. Gregory, Supp. March 13, viii.
Astro-Physics, on the State of Equilibrium of Stellar Atmospheres, Dr. Halm, 191–2
Astruc (A.), Method for the Alkalimetric Estimation of Disodium-methylarsenate or Arrhenal, 504
Astruc (Henri), Encyclopédie Scientifique des Aide-Mémoire, Le Vin, 245
Athens, Leonid Observations at, M. D. Eginitis, 143
Atkinson (Geo. Francis), First Studies of Plant Life, 75
Atlas Climatologique de l'Empire de Russie, Dr. Alexander Buchan, F.R.S., 554
Atlas of the Medulla and Midbrain, an, Florence R. Sabin, 172
Atmosphere: the Exploration of the Atmosphere over the Ocean, Dr. A. Lawrence Rotch, 4; the Exploration of the Atmosphere at Sea by means of Kites, A. Lawrence Rotch, 545; the Seasonal Variation of Atmospheric Temperature in the British Isles and its Relation to Wind Direction, W. N. Shaw, F.R.S., and R. Waley Cohen, 68; the Inert Constituents of the Atmosphere, Prof. W. Ramsay, F.R.S., at the British Association at Glasgow, 161; Further Observations and Conclusions in Relation to Atmospheric Transparency,

Hon. Rollo Russell, 191; Atmospheric Air capable of inducing Radio-activity, Prof. Geitel, 207
Atomic Weight of Calcium, New Determination of the, F. W. Hinrichsen, 281
Atomic Weights, International Table of, 400
Aucuba Japonica, on the Reserve Store of Carbohydrates in the Seed of, G. Champenois, 120
Auger (V.), Glyceroarsenic Acid, 335
Auld (S. J. M.), Benzeneazo-α-naphthol, 238
Aurora Borealis, Electromagnetic Theory of the, Charles Nordmann, 479
Auroræ, on Prof. Arrhenius' Theory of Cometary Tails and, Dr. J. Halm, 415
Australasian Association for the Advancement of Science, Inaugural Address by Captain F. W. Hutton, F.R.S., Evolution and its Teaching, 425

Deniges, 23; Dissolved Chlorides in Manchester Water, R. L. Taylor, 23; the Dilution of Acetylene for Heating Purposes, A. E. Munby, 30; Report of the Committee on Acetylene Generators, 472; Sulphimide, A. Hantzsch and A. Holl, 38; Pyrites and Marcasite, Dr. H. N. Stokes, 38; Electrolysis of Ammonium Chloride in Solution and Liquefied Ammonium, Henri Moissan, 47; Decomposition of Calcium- and Lithium-Ammonium by Ammonium Chloride, Henri Moissan, 47; Action of Metal Ammoniums on Hydrogen Sulphide, Henri Moissan, 72; Sodium-Ammonium Amalgams, Henri Moissan, 89; Sugars in Blood, MM. Lepine and Boulud, 47; Pinacoline, Maurice Delacre, 47; Constitution of Piceol, Ernest Charon and Démétrius Zamanos, 47; Formation of Vanillon, Henri Lecomte, 47; Ibogaine, J. Dybowski and Ed. Landrin, 48; Ibogine the Active Principle of a Plant of the Genus Tabernæmontana coming from the Congo, A. Haller and E. Heckel, 119: Researches on Cellulose from 1895–1900, Cross and Bevan, Dr. F. Mollwo Perkin, 52; Improved Sulphuretted Hydrogen Apparatus, Dr. F. M. Perkin, 62; New Method of Manipulating Liquid Gas in Sealed Tubes, Henri Moissan, 72; Formation of Ozone, A. Chassy, 72; Note on a Point of Chemical Nomenclature, Prof. Alfred Senier, 80; Celebration of the Jubilee of M. Berthelot, 80; Berthelot and the Metals of Antiquity, Dr. J. H. Gladstone, F.R.S., 82; Monomethylarsine, A. W. Palmer and W. H. Dehor, 89; Chemistry of the Albumins, 90; Combinations of Gold and Chlorine, Fernand Meyer, 96; Dioxyisopropylhypophosphorous Acid, C. Marie, 96; Oxidation of Unsaturated Alcohols by Contact Action, A. Trillat, 96; Blue and Green Coloration in Vertebrate Skins, MM. Camichel and Mandoul, 96; Memorial Lectures delivered before the Chemical Society, 1893–1900, 100; the Work of John Mayow, Dr. J. B. Cohen, 112; on the Properties of Barium, M. Guntz, 112; on a New Volatile Salt of Beryllium, G. Urbain and H. Lacombe, 119; Notes on Quantitative Spectra of Beryllium, Prof. W. N. Hartley, F.R.S., 190; on the Electrolytic Preparation of the Halogen Derivatives of Acetone, A. Richard, 119; on a Mixture of Hydrogen and Oxygen so Pure that it will not Explode, H. Brereton Baker, 119; the Union of Hydrogen and Oxygen, H. B. Baker, 430; Researches on the Law of Action of Sucrase, Victor Henri, 120; the Influence of Temperature on the Action of Nitric Acid on Metals, Dr. Alfred J. Ewart, 128; a Correction, 304; the Coal-Tar Colour Industry in Germany and England, 138; the Proteolytic Enzyme of Nepenthes, Prof. S. H. Vines, F.R.S., 141; Tin-Aluminium Alloys, Leon Guillet, 143; Alloys of Aluminium and Magnesium, O. Boudouard, 167; Composition of the Reserve Carbohydrates in the Albumen of Seeds of the Butcher's-broom, Georges Dubat, 143; a Dictionary of Dyes, Mordants and other Compounds used in Dyeing and Calico Printing, Christopher Rawson, Walter M. Gardner and W. F. Laycock, 148; the Inert Constituents of the Atmosphere, Prof. W. Ramsay, F.R.S., at the British Association at Glasgow, 161; State of Silicon in Cast Iron, P. Lebeau, 167; on a Practical Means of Obtaining Trichlorbutyl Alcohol, Marcel Guédras, 167; the Chemical Properties of Bacterial Gum Levan, Thos. Steel, 168; the Gum-fermentation of Sugar-Cane Juice, R. Grieg Smith, 168; Chemical Instruction and Chemical Industries in Germany, Dr. F. Mollwo Perkin, 174; on the Constituent of Peppermint Odour in many Eucalyptus Oils, Henry G. Smith, 192; Notes on the Sesquiterpene of Eucalyptus Oils, Henry G. Smith, 216; Die heterogenen Gleichgewichte vom Standpunkt der Phasenlehre, H. W. Bakhuis Roozeboom, 197; Pharmacopedia, a Commentary on the British Pharmacopœia, 1898, Edmund White and John Humphrey, 197; on Paper and Peroxide of Hydrogen, Dr. W. J. Russell, F.R.S., 200; Decomposition of Hydrogen Peroxide by Light, R. F. D'Arcy, 406; Action of Hydrogen Peroxide on Carbohydrates in Presence of Ferrous Salts, Messrs. Morell and Crofts, 477; Action of Hydrogen Peroxide on Oxide of Zinc, M. de Forcrand, 480; Death and Obituary Notice, Sir J. Henry Gilbert, LL.D., F.R.S., 205; Chemistry of Chlorophyll, Edward Schunck, F.R.S., 214; on Metallic Strontium and its Hydride, M. Guntz, 215; on Methylene Chlorobenzoate and Dibenzoate, Marcel Descudé, 215; Synthesis of Ketones, E. E. Blaise, 215; the Study of Fermentation Amyl Alchol, G. Bemont, 215; Chemical Society, 238, 309, 383, 430, 477, 527; Corydaline and Berberine, Dr. J. J. Dobbie and A. Lauder, 238; Magnetic Rotation of Polyhedral Alcohols, Dr. W. H. Perkin, sen., 238; Stereo-

isomeric Halogen Derivatives of α-benzoylcamphor, Dr. M. P. Foster and F. M. G. Micklethwait, 238; Brasilin and Hæmatoxylin, Prof. W. H. Perkin, jun., 238; Action of Phosphorus Trythiocyanate on Alcohol, Dr. A. E. Dixon, 238; Influence of Salts, &c., on Vapour Pressure of Aqueous Ammonia Solutions, Dr. E. P. Perman, 238; Action of Sodium Hypochlorite on Benzene Sulphoanilide, Dr. J. B. Cohen and J. T. Thompson, 238; Benzene-azo-α-naphthol, Dr. J. T. Hewitt and S. J. M. Auld, 238; on Ergot of Rye, Marcel Guédras, 239; the Laboratory of Henri Moissan, 252; Synthesis of Acetylenic Actions and β Ketonic Ethers, Ch. Moureu and R. Delange, 263; Effect of Hydrochloric Acid upon the Precipitation of Cuprous Sulphocyanide, R. G. Van Name, 263; Preparation and Properties of Potassium Hydride, Henri Moissan, 263; Action of Potassium Hydride on Ethyl Iodide and Methyl Chloride, Henri Moissan, 407; New Determination of the Atomic Weight of Calcium, F. W. Hinrichsen, 281; Preparation and Properties of the Hydride of Sodium, Henri Moissan, 287; Preparation and Properties of Strontium Hydride, Henri Gautier, 288; Chemical Equilibrium of the Iron-Carbon Systems, Georges Charpy and Louis Grenet, 288; Action of Mixed Organo-magnesium Compounds upon Trioxymethylene, V. Grignard and L. Tissier, 288; Elementary Chemical Theory, G. H. Martin, 296; Conditions of Formation of the Oceanic Salt Deposits, J. H. van 't Hoff, 304; the Validity of the Ionisation Theory, Louis Kahlenberg, 305; Dr. H. M. Dawson, 414; the Constitution of Hydrocyanic, Cyanic and Cyanuric Acids, Dr. F. D. Chattaway, Mr. Wadmore, 309; the Radio-active Emanation produced by Thorium Compounds, Prof. Rutherford, Mr. Soddy, 309; Modification of Zeisel's Method for the Estimation of Methoxyl Groups, Dr. J. T. Hewitt, T. S. Moore, 309–10; a new Colour Reaction of Hydroxylamine, W. C. Ball, 310; Myricetin, A. G. Perkin, 310; the Colouring-matters of Green Ebony, A. G. Perkin and S. H. C. Briggs, 310; the Action of Methylene Iodide on Aryl and Naphthylamines, Diaryl Methylene Diamines, Acridines and Naphthacridines, Dr. Senier and Mr. Goodwin, 310; the Polymerisation of Cyanic Acid, Dr. Senier and T. Walsh, 310; on some Properties of Fused Lime, Henri Moissan, 311; on some Physical Properties of Hydrogen Selenide, MM. de Forcrand and Fouzes-Diacon, 311; Vapour Pressures of Hydrogen Selenide and the Dissociation of its Hydrate, MM. de Forcrand and Fonzes-Diacon, 335; Comparison between the Properties of Hydrogen Selenide and those of Hydrogen Sulphide, MM. de Forcrand and Fonzes-Diacon, 359; on the Assimilation of Sugar and of Alcohol by *Eurotyopsis Gayoni*, P. Mazé, 312: Phosphorus in the Invertebrates, Jean Gautrelet, 312; Chemical Modifications in Plants submitted to the Influence of Sodium Chloride, E. Charabot and E. Hébert, 312; a College Text-book of Chemistry, Ira Remsen, 314; Lithium Antimonide and Preparation of some Alloys of Lithium, P. Lebeau, 335; Action of Lithium-ammonium on Antimony and on the Properties of the Antimonide of Lithium, P. Lebeau, 359; Preparation of Tantalum in the Electric Furnace and its Properties, Henri Moissan, 335; Lehrbuch der Chemie und Mineralogie, Prof. G. Siebert, 317; Suggested Modification of the Sign of Equality in Chemical Notation, Dr. Hugh Marshall, 335; Glyceroarsenic Acid, V. Auger, 335; Mechanism of the Formation of the Purple of Molluscs, Raphael Dubois, 335; Action of Nitric Acid upon Trichloro- and Tribromo-veratrol, H. Cousin, 359; New Synthesis of Formic Acid, Henri Moissan, 359; Chemistry of Pigments, E. J. Parry and J. H. Coste, 363; Nature of Red Phosphorus, Dr. R. Schenck, 374; Liquid Sulphur Dioxide as a Solvent, Messrs. Walden and Centners, 374; the Stratification of Hydrogen, Sir William Crookes, F.R.S., at the Royal Society, 375; Method for Determining the Concentration of Hydrogen Ions in Solution, H. O. Jones and O. W. Richardson, 407; Composition of Brittle Platinum, Prof. Hartley, F.R.S., 383; Conversion of 1-hydroxycamphene, into β-halogen Compounds of Camphor, Dr. M. O. Forster, 383; Solubilities of the Calcium Salts of the Lower Fatty Acids, Dr. Lumsden, 383; on the Union of Hydrogen and Chlorine, Messrs. Mellor and Anderson, 383; Resolution of Trimethylhydrindonium Hydroxide into its Optically Active Constituents, Prof. F. S. Kipping, F.R.S., 383; Resolution of Methylbenzylacetic Acid into its Optical Isomerides, Prof. S. F. Kipping, F.R.S., 383; *d*-Methylhydrindon, Prof. F. S. Kipping, F.R.S, 383; on the "Hornsilvers," G. T. Prior, L. J. Spencer, 383; the Influence of Temperature on Association in Benzene Solution, Dr. W. R. Innes, 383; Magnetic Rotation of Ring Compounds, Camphor Limonene, Carvene Pinene, &c., Dr. W. H. Perkin, sen., 383; on the Constitution of Certain Organic Nitrates, Messrs. Marshall and Wigner, 383; the Development of Chemistry, Prof. F. W. Clarke, 399; International Table of Atomic Weights, 400; Oxidation in Presence of Iron, H. J. H. Fenton, 406; Formation of Dinitrophenoxazines, J. C. Crocker, 407; Interaction of Thiocyanates, Picryl Chloride and Alcohols, J. C. Crocker, 407; Oxidation of Glucosone to Trioxybutyric Acid, R. S. Morrell, 407; New Methods of Preparation of Ethane and Methane, Henri Moissan, 407; the Slow Oxidation of Methane at Low Temperatures, Dr. Bone and R. V. Wheeler, 477; Praseodidymium Chloride, Camille Matignon, 408; Practical Chemistry, Abegg and Herz, 410; Electrical Manufacture of Carbon Bisulphide, 420; Enzyme Action, Prof. A. J. Brown, 430; Velocity of Hydrolysis of Starch by Diastase, H. T. Brown, F.R.S., and T. A. Glendinning, 430; Chemical Change Produced by the Immersion of Lead in Distilled Water, Dr. F. Clowes, 430; Bases contained in Scottish Shale Oil, F. C. Garrett and J. A. Smythe, 430; on the Constitution of Dibutylic and Diœnanthylic Alcohols, Marcel Guerbet, 431; on some Reactions obtained with the aid of Magnesium Amalgam, L. Meunier, 431; on some Derivatives of Methyl-nonyl-ketone, H. Carette, 431; on the Analysis of Ceramic Products, V. de Luynes, 431–2; Composition of the Gases in Drains, M. Hanriot, 432; the Experimental Study of Gases, Morris W. Travers, 461; Jahrbuch der Chemie, 438; Death of Prof. Maxwell Simpson, F.R.S., 442; Obituary Notice of, Prof. A. E. Dixon, 515; Catalytic Power of Metallic Nickel Synthesis of Methane based on Reaction of Metallic Nickel and Hydrogen, MM. Sabatier and Senderens, 446; Catalysis, Prof. Ostwald, 522; on the Crystallisation of Iron Peroxide, Alfred Ditte, 455; Composition of an Antique Vase, M. Berthelot, 455; Researches on Silicide of Calcium, MM. H. Moissan and W. Dilthey, 455; Recombination of the Ions in Gases, P. Langevin, 455; the Specific Heat and Atomic Weight of Vanadium, C. Matignon and E. Monnet, 455; New Reactions of Organo-Metallic Derivatives, E. E. Blaise, 455; the Resolution of Pheno-α-aminoheptamethylene into its Optical Merides, Prof. F. S. Kipping, F.R.S., and A. E. Hunter, 477; Myrticolorin identical with Osyritrin, A. G. Perkin, 477; the Nitration of *sym.* Trihalogen Anilines, Dr. Orton, 477; the Cloëz Reaction, Dr. Chattaway and J. M. Wadmore, 477; Mesoxalic Semi-aldehyde, Messrs. Fenton, F.R.S., and Ryffel, 477; *m*-Nitrobenzoyl Camphor, Dr. M. O. Forster and Miss F. M. G. Micklethwait, 477; Modification of Rose's Method of Separating Cobalt and Nickel, R. L. Taylor, 478; Experiments for Discovering whether Faraday's Law may be considered as applying to Gases, D. L. Chapman and F. A. Lidbury, 479; New Hydride of Silicon, H. Moissan and S. Smiles, 479; on the Separation of Galactose and Glucose by the *Saccharomyces Ludwigii*, Pierre Thomas, 480; New Phosphate of Soda, H. Joulie, 480; Der Naturwissenschaftliche Unterricht in England, insbesondere in Physik und Chemie, Dr. Karl T. Fischer, 481; Method for the Alkalimetric Estimation of Disodium-methylarsenate or Arrhenal, A. Astruc, 504; the Supposed Binaphthalene-glycol, R. Fosse, 504; Derivatives of Arabinose, G. Chavanne, 504; the Pseudo-Acids, P. Th. Müller, 504; Studies on Vegetable Earth, Th. Schloesing, 504: Conservation of Refractive Energy in Mixtures of Alcohol and Water, A. Leduc, 504; the Raoult Memorial Lecture delivered by Prof. Van 't Hoff 516; Death of G. F. Wilson, F.R.S., 516; on certain Chemical and Physical Properties of Hæmoglobin, read before the Royal Society by Dr. Arthur Gamgee, F.R.S., 520; the Constitution of Hydrogen Cyanide, J. Wade, 527; Method of Determining the Ratio of Distribution of a base between two Acids, Messrs. Dawson and Grant, 527; the Molecular Complexity of Acetic Acid in Chloroform Solution, H. M. Dawson, 527; Existence of Polyiodides in Nitrobenzene Solution, Messrs. Dawson and Gawler, 527; Preparation of Sulphamide from Ammonium Amido Sulphite, Prof. Divers, F.R.S., and Mr. Ogawa, 527; Hypoiodous Acid, R. L. Taylor, 527; Quercetazetin, A. G. Perkin, 527; a Monosodium Acid Orthophosphate,

H. Giran, 528; some new Compounds of Methylene, Marcel Descudé, 528: Action of Sulphurous Acid as an Antidote against *la casse* in Wines, J. Laborde, 528; the Boiling-Point of Selenium, D. Berthelot, 528; the direct Hydrogenation of the Oxides of Carbon in presence of various finely divided Metals, MM. Paul Sabatier and J. B. Senderens, 528; Method of calculating Solubilities and the Equilibrium Constants of Chemical Reaction and on a Formula for the Latent Heats of Vaporisation, Alexander Findlay, 547; Action of Silver Salts on a Solution of Ammonium Persulphate, Dr. Hugh Marshall, J. K. H. Inglis, 551; Outlines of Electro-chemistry, H. C. Jones, 557; New Application of the Electric Furnace, C. B. Jacobs, 572; on the Relation $L+S/T=Q/T=K$, M. de Forcrand, 579; Classification of the Atomic Weights of Neon, Argon, Krypton and Xenon, H. Wilde, 579–80; on a Type of Compounds of Glucinum, H. Lacombe, 580; Constitution of the Chlorhydrins, Marc Tiffeneau, 580; Nitration of Furfurane, M. Marquis, 580; New Mode of Preparation of Oxygen, George F. Jaubert, 580; Ferments and their Actions, Carl Oppenheimer, Dr. A. C. Houston, 582; the Rhodin Cell Electrolytic Alkali Works at Sault, Sainte Marie, Ontario, B. E. F. Rhodin, 593; Composition of Gaseous Hydrates, M. de Forcrand, 603; the Action of Hydrogen upon Strontium Amalgam, M. Guntz, 603; on Oxyisopropylphosphinic Acid, C. Marie, 604; Composition of the Amidotariric Acids, M. Arnaud, 604; Roscoe-Schörlemmer's ausführliches Lehrbuch der Chemie. Jul. Wilh. Brühl, Prof. R. Meldola, F.R.S., Supp. November 14, 1901, iii.

Sugar-Cane Juice, the Gum-fermentation of, R. Grieg Smith, 168
Sugar-Cane Plants, Insect and other Diseases of the Cacao and, in the West Indies, 110
Sugar Crystals in Bulk, the Deterioration of Raw and Refined, R. Greig Smith, 239
Sulphur Dioxide as a Solvent Liquid, Messrs. Walden and Centners, 374
Summary of Progress of the Geological Survey, 204
Sun: Planetary Influence on Sun-Spot Period, 39; the Total Solar Eclipses of September 9, 1904, Dr. A. M. W. Downing, F.R.S., 30; the Annular Eclipses of the Sun, November 10-11, 1901, 62; M. A. de la Baume Pluvinel, 232; Observations in Lower Egypt of the Annular Eclipse of the Sun of November 11, 1901, A. de la Baume-Pluvinel, 215; the Total Solar Eclipse, May 18, 1901, 210, 283; Magnetic Observations during, 210; Dr. W. Van Bemmelen, 305; Results of International Magnetic Observations made during the Total Solar Eclipse of May 17-18, 1901, Dr. L. A. Bauer, 246; Simultaneous Visibility of Sun and Total Lunar Eclipse, Dr. C. Hildebrand, 305; Hertzian Waves Emanating from the Sun, Charles Nordmann, 359; the Zodiacal Light and Sun Pillars, Rev. Guy J. Bridges, 439; Wm. A. Knight, 439; Sun Pillars, W. H. Graham, 465; Dr. G. Johnstone Stoney, F.R.S., 465; H. B. Knowles, 536; G. Paul, 511; Hon. R. Russell, 512; Sir W. J. Herschel, 512; Catherine O. Stevens, 512; Dr. Vaughan Cornish, 560; Disturbance of Corona in Neighbourhood of Prominences, Prof. C. D. Perrine, 351; Origin of Disturbance in Corona, May 17-18, 1901, 499; a New Solar Theory, Dr. J. Halm, 351; the Spectrum of the Chromosphere, S. A. Mitchell, 423; the Effective Temperature of the Sun, Dr. W. E. Wilson, F.R.S., 428; Distortion of Sun's Disc at Horizon, Prof. W. Prinz, 520
Sunshine and Surf: a Year's Wanderings in the South Seas, D. B. Hall and Lord Albert Osborne, 57
Surgery: Death of Sir William MacCormac, Bart., K.C.B., 109; Obituary Notice of, 131
Surveying, the Hammer-Fennel Tacheometer, Prof. Hammer, 14; Indian Surveys, 424
Swarm of Velella: Isaac C. Thompson, 560; Prof. Ch. S. Sherrington, F.R.S., 586; Rose Haig Thomas, 586
Swinburne (James), on the Factors of Heat, 309
Swinnerton (H. H.), Morphology of the Skull of the Bony Fishes, 573
Symon's Meteorological Magazine, 87, 178, 280, 421
Symons (G. J.), Bequest to the Royal Meteorological Society, 135

Tacheometer, the Hammer-Fennel, Prof. Hammer, 14
Tahiti, Dr. S. P. Langley's Visit to, 180
Tales of a Dying Race, Alfred A. Grace, 389
Tantalum in the Electric Furnace and its Properties, Preparation of, Henri Moissan, 335
Tarenetsky (Prof. A.), Craniology of the Aleutians, &c., 445
Tarr (R. S.), Tarr and McMurry's Geographies, Supp. March 13, 1902, x
Tate (Prof., Ralph), Death and Obituary Notice of, 11
Tattooing of Women in the Laughlan Islands, Prof. G. Thilenius, 445
Taxation, Theory of Progressive, G. Cassel, 208
Taylor (R. L.), Dissolved Chlorides in Manchester Water, 23; Modification of Rose's Method of Separating Cobalt and Nickel 478; Hypoiodous Acid, 527
Teachers' Manual of Object Lessons for Rural Schools, Senior, the, V. T. Murché, 583
Teaching of Mathematics in Public Schools, the, 258
Teaching of Mathematics, the, C. J. Forth, 272
Teaching, Reform in the Mathematical, 457; C. S. Jackson, 558; Frank L. Ward, 558; Discussion on, at the Meeting of the British Association at Glasgow, 457
Technical Education, Foreign Competition and, Arthur G. Green, 156
Technical Schools for Rural Districts, 106
Teesdale, the Glaciation of, A. R. Dwerryhouse, 310
Tegetmier (W. B.), Variation in Fowls, 152
Telegraphy, Wireless: Wireless Telegraphy and English Channel Lightships, 109; the "Armorl" Electro-capillary Relay, 129; Marconi's Signalling from England to America by Wireless Telegraphy, 158; Marconi's Transatlantic Experiments, 228; Proposed Installation of Marconi's System at the Mouth of the St. Lawrence River, 348; Kites and Wireless Telegraphy, Dr. A. Lawrence Rotch, 198; Wireless Telegraphy, Prof. F. Braun, 372; Position and Promise of Wireless Telegraphy, 394; Curious Anticipation of a Magnetic Means of Communication, Strada, 397; Further Developments in Wireless Telegraphy, 416; Wireless Telegraphy, G. W. de Tunzelmann, Supp. November 14, 1901, x
Teleology, Sinnesorgane in Pflanzenreich zur Perception Mechanischer Reize, Dr. G. Haberlandt, Francis Darwin, F.R.S., 529
Telephone, on the Use of the, for Investigating the Rhythmic Phenomena of Muscles, Sir John Burdon Sanderson, 114
Telephony Without Wires, E. Ducretet, 287
Telephotography, Elementary, Ernest Marriage, 244
Telescopes: Spectra of Bright Southern Stars, Photographed with the 13-inch Boyden Telescope as a Part of the Henry Draper Memorial, Annie J. Cannon, A. Fowler, 155; Focussing of a Collimator or a Telescope by Means of the Measurement of a Parallax, G. Lippmann, 263; Pleasures of the Telescope, Garrett P. Serviss, 343; the New Bruce Spectrograph for the Yerkes Refractor, 374
Temperature: the Influence of Temperature on the Action of Nitric Acid on Metals, Dr. Alfred J. Ewart, 128; a Correction, 304; Production and Maintenance of Low Temperatures, M. d'Arsonval, 167; a New Method for the Measurement and Recording of High Temperatures, André Job, 263; Temperature and Glacial Periods, H. N. Dickson, 229; on the Factors of Heat, James Swinburne, 309; Results of the Maximum and Minimum Temperatures at Hamburg during the Last Quarter of a Century (1876-1900), Dr. Grossman,

323; Action of Temperature on the Mineral Absorption in Etiolated Plants, 504; Temperature of Insects: Experimentelle entomologische Studien vom physikalisch-chemischen Standpunkt aus, Prof. P. Bachmetjew, 101
Temple (Sir Richard, F.R.S.), Death of, 471
Tercentenary of Tycho Brahe's Death, Dr. J. L. E. Dreyer, Prof. Bohuslav Brauner, 5
Terre, La Face de la, Eduard Suess, 145
Terrestrial Day, Length of the, R. S. Woodward, 113
Test Papers in General Knowledge, H. S. Cooke, 533
Texas Mineral Survey, Report on Sulphur, Oil and Quicksilver in Trans-Pecos, W. B. Phillips, 594
Textile Markings on Primitive Pottery, W. H. Holmes, 350
Thayer (A. H.), the Meaning of the White Undersides of Animals, 597
Theorems Concerning Geometrical Figures in Space *n* Dimensions, G. H. Knibbs, 335
Theory of Progressive Taxation, G. Cassel, 208
Therapeutics: Treatment of Rickets by Cod Liver Oil containing Lecithin, G. Carriere, 604; Prof. Bacelli's New Treatment for Foot and Mouth Disease, 59; on the Salutary Effects of Potatoes in Diabetics in High Doses, A. Mossé, 168
Therapy: Use of Organic Arsenic and Phosphorous Compounds in the Treatment of Tuberculosis, A. Mouneyrat, 504
Thermal Measurement of Energy, the, E. H. Griffiths, F.R.S., 342
Thermoelectricity of Steels and Nickel-steels, G. Belloc, 288
Thermometry: Gas Thermometry, II., Dr. P. Chappuis, 93; on a Petroleum Ether Thermometer for Use at Extremely Low Temperatures, L. Baudin, 215; the History of Fahrenheit's Thermometer, Sir Samuel Wilks, F.R.S., 348; the Origin of the Scale of Fahrenheit's Thermometer, Gilbert S. Ram, 391
Thilenius (Prof.), Polynesians' Alia or Double Canoe, 256; Tattooing of Women in the Laughlan Islands, 445
Thiselton-Dyer (Sir W. T., F.R.S.), Cherry Disease, 296, 413; the Education Bill, 584
Thomas (A. P. W.), Preliminary Account of the Prothallium of Phylloglossum, 214; the Affinity of Tmesipteris with the Sphenophyllales, 358

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"*To the solid ground
Of Nature trusts the mind which builds for aye.*"—WORDSWORTH.

THURSDAY, NOVEMBER 7, 1901.

THE HIND-BRAIN OF THE MONOTREME.

Die Medulla Oblongata und die Vierhügelgegend von Ornithorhynchus und Echidna. Von A. Koelliker. Pp. vi + 100. (Leipzig: Engelmann, 1901.) Price 16*s.*

DETAILED knowledge of the brain of the Monotreme has in recent years been considerably extended by the works of Profs. Elliot Smith, of Cairo, and Ziehen, of Jena. Material suitable for successful prosecution of microscopical research in this field is necessarily rare. It is a matter for congratulation that such material should have reached the hands of a veteran histologist, Prof. v. Kölliker. His monograph deals with the arrangement of nerve-fibre bundles and of nerve-cell groups in the mid-brain and hind-brain of ornithorhynchus and of echidna respectively. The study is based on transverse sections stained with hæmatoxylin by the Weigert method for nerve-fibres. The ornithorhynchus brain furnished for the regions studied a series of 1088 sections. Detailed drawings under defined enlargement are given for sections at eighteen of the levels. Among the points of interest ascertained the following appear the chief.

Both monotremes offer in common certain features in contradistinction to other mammalia. Noteworthy among these are the subjoined.

The fourth ventricle extends very far distally, so far, in fact, that instead of the anterior half of the cell-group of origin of the hypoglossal nerve, the whole length of that cell-group lies practically uncovered in the floor of the ventricle. The hypoglossal cell-group lies, not next the raphe and under the longitudinal bundle, but away at the side of the ventricle.

The root of the cochlear nerve enters the bulb by piercing it ventral to the peduncle of the cerebellum; none of its fibres wind round the peduncle. But the so-called striæ acusticæ exist nevertheless on the dorsal aspect of the bulb.

The facial nerve has, in addition to its regular nucleus, a second widely separate and dorsal to that, near below the genu of the nerve root. The sensory root of the trigeminus is very large, and enters the brain entirely anterior to the pons.

The pons is poor in cell-groups proper to itself. In echidna there are some cell-groups in its lateral portions as well as in the median, but in ornithorhynchus there are no lateral cell-groups at all.

The great system of fibres—the "fillet" or sensory system—ascending toward the brain and fed by secondary relays from the usual recipient afferent cell-groups is well developed, and exhibits the general arrangement obtaining in higher mammals. On the other hand, the system of fibres—the pyramidal—descending from the hemispheres to form connections with the efferent nuclei is so poorly developed that its very existence is not absolutely certain, at least for ornithorhynchus. It is of interest to note that the great efferent cerebral system can coexist in so meagre an extent in forms which possess an afferent spino-cerebral system so extensive. Thus as a permanent condition we have a state of things similar to that which regularly forms a transient stage in the development of the higher type of mammalian nervous system.

Among features of interest offered by the two brains individually, and therefore to be considered more or less apart each from the other, are the following:

In ornithorhynchus, with its small cochlear nerve, there is discoverable only a mere trace of any superior olive. In echidna, with its large cochlear nerve, the superior olive is a structure of considerable extent.

In echidna a large system of fibres passes along the lateral region of the bulb to the outer side of the sensory root of the trigeminus. These fibres in the upper pontine levels bend inward, decussate, and ascend again in the *pes pedunculi cerebri* of the crossed side. They are traceable at least as far as the optic thalamus. Kölliker urges that it is a sensory spino-cerebral system, but the merely anatomical method employed affords no trustworthy guide to the functional direction of the path.

The central nervous system of echidna represents, on the whole, a grade of development distinctly superior to that of ornithorhynchus. Traces of a pyramidal system fairly distinct though very scanty can in echidna be

followed into the proximal end of the spinal cord. In ornithorhynchus, Ziehen could not satisfy himself about the existence of any pyramidal system. Prof. Kölliker believes he can distinguish a pyramidal decussation in ornithorhynchus and that the fibres of it plunge mainly into the dorsal column of the spinal cord (as in the rat and guinea-pig) and not into the lateral column, as in the generality of mammals. But the description he gives is a very unsatisfactory one, and no mention is made of his data for discrimination between the undoubtedly existent fillet decussation and the equivocally existent pyramidal. Moreover, he admits that he finds in ornithorhynchus no trace of longitudinal fibres passing anywhere along the pons. In arguing for the existence of a pyramidal system, he omits mention of what to most minds forms the strongest argument yet adducible, namely, that, as shown by Prof. C. J. Martin, of Melbourne, excitation of a certain region of the cerebral cortex of ornithorhynchus evokes movement of the crossed fore-limb.

The large extent and specially sentient character of oral-facial surface in ornithorhynchus prepares the observer for a large recipient nucleus in the bulb to subserve the huge sensory root of the trigeminus. This root and its recipient nucleus form a huge projection either side the bulb—the tuberculum quinti, well shown in a figure reproduced from Elliot Smith. Prof. Kölliker finds fibres of this root traceable to the nuclei of the *hypoglossus*, *vago-glossopharyngeus* and *abducens*, as well as to that of the trigeminus itself. From the recipient nucleus of trigeminus he traces fibres to the median fillet, and so to the optic thalamus. C. S. S.

DIVERGENT SERIES.

Leçons sur les Séries Divergentes. Par Émile Borel. Pp. viii+184. (Paris: Gauthier-Villars, 1901.) Price fr. 4.50.

TO make the object of this work intelligible, it is necessary to recall a few facts concerning infinite series in general. Suppose we have a sequence

$$u_1, u_2, u_3, \ldots u_n, \ldots \qquad (U)$$

where u_1, u_2, &c., are analytical expressions constructed by a definite rule. Let $s_n = u_1 + u_2 + \ldots + u_n$; then we have a derived analytical sequence

$$s_1, s_2, s_3, \ldots s_n, \ldots; \qquad (S)$$

this is a definite analytical entity, and its properties are implicitly fixed by those of the former sequence. The expressions u_n, s_n are, of course, functions of n; we may suppose, for simplicity, that, besides this, they involve, in addition to definite numerical constants, a single analytical variable, x. If we assign to x a numerical value, S becomes an arithmetical sequence, and three principal cases arise, according to the behaviour of s_n when n increases indefinitely. If s_n converges to a definite limit s we say that this is the sum of the series $u_1+u_2+u_3+\ldots$, and write $s=\sum_1^\infty u_n$; but the ultimate value of s may be either indeterminate or infinite. In the second case Σu_n has no definite meaning; in the third we may say, if we like, that Σu_n is infinite, but this infinite sum is not a quantity with which we can operate, and presents no special interest.

When the series Σu_n and Σv_n are absolutely convergent we can add and multiply them according to the rules

$$\Sigma u_n + \Sigma v_n = \Sigma(u_n + v_n)$$
$$\Sigma u_n \times \Sigma v_n = u_1 v_1 + (u_1 v_2 + u_2 v_1) + (u_1 v_3 + u_2 v_2 + u_3 v_1) + \ldots$$
$$= \sum_n \sum_r (u_r v_{n+1-r}):$$

now the sequences

$$u_1+v_1,\ u_2+v_2,\ \ldots\ u_n+v_n,\ \ldots \qquad (A)$$
$$u_1v_1,\ u_1v_2+u_2v_1,\ \ldots\ u_1v_n+u_2v_{n-1}+\ldots+u_nv_1,\ \ldots \qquad (B)$$

can be constructed, whether or not the sequences $(u_1, u_2, \ldots)$ and $(v_1, v_2, \ldots)$ are convergent; the question therefore arises whether it is possible, even when the series Σu_n, Σv_n are divergent, to associate with the sequences $(u_1, u_2 \ldots)$ and $(v_1, v_2, \ldots)$ certain finite and determinate functions U, V in such a way that U+V and UV may be *by the same rule of correspondence* associated with the sequences (A) and (B) above.

Among the various ways in which this can be done, M. Borel's method of exponential summation is particularly interesting. Briefly it is this: let

$$u(a) = u_0 + u_1 a + \frac{u_2 a^2}{2!} + \frac{u_3 a^3}{3!} + \ldots + \frac{u_n a^n}{n!} + \ldots$$

then the function

$$s = \int_0^\infty e^{-a} u(a)\, da$$

is defined to be the *exponential sum* of the series $u_0+u_1+u_2+\ldots$. When Σu_n is convergent, s coincides with the sum in the ordinary sense; the important point is that s may be finite even when Σu_n is divergent; the series is then "exponentially summable"—*absolutely* so, if

$$\bar{s} = \int_0^\infty e^{-a} \mid u(a) \mid da$$

is a convergent integral. M. Borel proves that (in the case of absolute summability) if U, V are the exponential sums of Σu_n and Σv_n, then U+V and UV are the exponential sums of the series whose terms are given under (A) and (B) above; in other words, the formal laws of rational operation are satisfied. In a similar sense, an absolutely summable series may be differentiated any number of times.

As an example of the practical value of these results, suppose we have a differential equation $F(y, y', y'', \ldots)=0$ in which $y, y', y'' \ldots$ enter rationally: then, if this is found to be formally satisfied by a series Σu_n, which, although divergent in the ordinary sense, is exponentially summable, the exponential sum is actually a solution of the differential equation.

In Chapter iv. M. Borel applies the idea of exponential summation to an interesting problem in function-theory. Suppose we have a power-series

$$u_0 + u_1 x + u_2 x^2 + \ldots$$

which is convergent within a circle of finite radius, but divergent outside of it. Within the circle, this series defines a function of x, say $f(x)$; within the same region the series is exponentially summable, and its sum is $f(x)$. But the exponential sum may exist and be finite in a region *larger* than the circle of convergence of the power-series; in this case the exponential sum is an analytical continuation of $f(x)$ outside the circle, and the new region

of summability is shown to comprise an area bounded by a (finite or infinite) number of straight lines, each of which goes through a critical point. This new region M. Borel calls the *polygon of summability*. An obvious question arises here; does the continuation of $f(x)$ obtained by exponential summation necessarily coincide with one obtained by other methods, for example Weierstrass's? In some cases it certainly does; for instance, when $f(x)$ is a rational function of x, or one branch of an algebraic function.

So far it has been supposed that the object of inquiry is in the first instance a series given by the law of construction of its terms; and the main result has been to show how, in certain cases where the series is divergent in the ordinary sense, it may be associated with a finite function, called its sum (in an extended sense), which the series so far represents that relations satisfied formally by the series are actually and arithmetically satisfied by its sum. But there is another side of the question which is of equal importance, especially from the practical point of view. We may have a function explicitly or implicitly defined by certain properties, and try to obtain a series which for purposes of computation or otherwise may be regarded as its equivalent. A typical illustration is afforded by the ordinary process of solving differential equations by series; here we have a uniform method which, if it does not fail altogether, leads us to a power-series, formally satisfying the equation, but not necessarily convergent. Exponential summation, when it is applicable, enables us to obtain a solution from the merely formal equivalent. In this connection we have Poincaré's theory of asymptotic series, which is expounded by M. Borel in Chapter i. Independently of its convergence, the expansion

$$c_0 + \frac{c_1}{x} + \frac{c_2}{x^2} + \ldots + \frac{c_n}{x^n} + \ldots$$

is said to represent $f(x)$ asymptotically if

$$x^n \left[f(x) - c_0 - \frac{c_1}{x} - \frac{c_2}{x^2} - \ldots - \frac{c_n}{x^n} \right]$$

vanishes when x is infinite. Asymptotic expansions may be combined by the ordinary formal rules of rational operations, and the result is asymptotically equivalent to the corresponding combination of the functions represented. These considerations justify the use of semi-convergent series in computation; the classical example occurs in the theory of the gamma function. It must be carefully observed, however, that although the asymptotic expansion (if it exist) of a definite function is itself definite, we *cannot* infer the existence of a definite function corresponding to a given expansion $\Sigma c_n x^{-n}$: the reason of this rather paradoxical result is that innumerable functions (for instance e^{-x}) lead to an asymptotic expansion with zero coefficients throughout.

In Chapter ii. M. Borel discusses the results contained in Stieltjes's memoir (*Annales de la Faculté des Sciences de Toulouse*, tt. viii. ix.), and in Chapter v. deals with the polynomial expansions due to Mittag-Leffler. Interesting as they are, it seems hopeless to try to analyse these chapters within the compass of a review; they are, indeed, themselves of the nature of summaries, and will be best appreciated by those readers who accept M. Borel's invitation to consult the original memoirs. Attention may, however, be called to the author's estimation of these researches. It is, in effect, that the memoir of Stieltjes, though of great originality and suggestiveness, is of restricted application and not likely to lead to a general theory; and that, on the other hand, while Mittag-Leffler's theory does not immediately afford a calculus of divergent series, in the proper sense of the term, it may very probably lead to one. It should be added that M. Borel himself has made substantial contributions to this theory of polynomial expansions; some of them appear for the first time in the present volume.

The fact is that most of the field traversed in this very attractive course is of recent discovery, and we cannot expect to be presented with a complete and symmetrical doctrine all at once. Let us be thankful that M. Borel, himself one of the pioneers on this novel route, has so clearly and impartially indicated the progress that has hitherto been made.

OUR BOOK SHELF.

The Chemical Essays of Charles-William Scheele. Pp. xxx + 294. (London: Scott, Greenwood and Co., 1901.) Price 5*s*. net.

THIS is a reprint of Dr. Beddoes' translation of Scheele's essays, which was published in 1786 by John Murray and may still be picked up occasionally in second-hand book shops. The reproduction is faithful even to the mis-spelling of Priestley's name in Beddoes' preface. Between this preface and the essays, however, there now appears a memoir of the life and work of Scheele, written for the reissue by Mr. John Geddes McIntosh. Mr. McIntosh presumably has inspired the reissue of the essays, and if this will be the means of getting them more generally read by students of chemistry, he may so far prove a benefactor.

Of the essays themselves it is hardly necessary to say anything. The facts they establish belong for the most part to what is now very elementary chemistry and the phlogistic hypothesis with which the explanations are involved did not long outlive Scheele; but the spirit which breathes in these essays and the method they inculcate can never grow commonplace or antiquated.

The strict fidelity to experiment, the rare sagacity, the scrupulous and minute observation and the extraordinary experimental skill combine to make Scheele a model for all time. When we add to this the pathos of his early struggles, the simplicity of his blameless life and the nobility of his untimely death, there can be no wonder that Scheele is reckoned a hero among chemists.

It cannot be said that the memoir which accompanies these essays is worthy of the subject. Mr. McIntosh has apparently considerable enthusiasm for the solid virtues of Scheele and for the material outcome of Scheele's discoveries, but he shows little critical insight or literary taste. Speaking, for example, of the discovery of chlorine, he says: "Let us now glance at the radical errors of the French school, the chief of whom was Berthollet, the man who was the first to make practical application of Scheele's discovery, and, as is usually the case with such men, they propound a theory of their own, so that some at least of the merit, if not all of the original discovery, may descend upon their own mantle."

The violence here done to Berthollet, to the rules of English composition, and to a time-honoured metaphor is very remarkable.

On the following page it is stated to be "a well-known fact at the present day" that the product of distilling fluorspar and sulphuric acid in a glass retort is gaseous hydrofluosilicic acid.

The essay concludes with a comparison of Scheele with Shakespeare, somewhat to the disparagement of the poet, and with a very comical lament that so few people ever visit either Scheele's birthplace, "if it still be in existence," or his shrine at Köping, "where he died and where presumably his remains are interred." One might even suspect that Mr. McIntosh had not been there. A. S.

Use-Inheritance; Illustrated by the Direction of Hair on the Bodies of Animals. By W. Kidd. 8vo. pp. 47. Illustrated. (London: A. and C. Black, 1901.) Price 2s. 6d. net.

EVERY naturalist who has studied the ungulate mammals must have been struck with the curious variation in the direction of the hair which occurs even in closely-allied species, and has probably been much puzzled to account for these differences. Why, for instance, do the hairs on the back of all the Asiatic buffaloes point towards the head and those of their African allies in the opposite direction? In the former animals, as in all analogous instances, a whorl (in this case on the haunches) marks the point where the change in the direction of the hairs from the normal backward slope occurs. In the work before us the author, although he has not attempted to give a reason for the variation in the hair-slope of closely allied species, has done good service by classifying these "whorls" and "featherings," as typified in the horse. He has also shown that these features always occur at spots where two or more muscles are acting against one another, as is well exemplified on the forehead of the horse. It is therefore suggested that the production of such whorls has a dynamical origin. It is noteworthy that while whorls and featherings are very commonly developed in short-haired mammals, they are either absent or rudimentary in those with long hair.

The main argument of the book is, however, connected with certain peculiarities of the hair-slope in man. In normal instances this slope on the back of the head and neck diverges obliquely from the middle line, somewhat after the simian fashion. But in a second, or "exceptional," type the direction is just the reverse of this. It is suggested that while the normal type has been directly inherited from simian ancestors, the exceptional type (which is considered to be an acquired one) has been derived from the female line. It is further shown than on the human back the direction of the hair-slope is quite different from that which obtains in all apes and monkeys. "This aberration of hair-slope I have suggested," writes Dr. Kidd, "to be produced by the habit which man has of spending about a third of his life, during sleep, in lying mostly on his side, and, for some millenniums at least, with some sort of rest for his head."

These peculiarities in the hair-slope of man and other animals, adds the author, are congenital and not due to selection; hence, unless originally created with the forms of life in which they occur, they must have been produced in their ancestors by use or habit. From this it follows that, if the creation hypothesis be discarded, in this particular instance, at any rate, acquired characters are inherited.

While claiming recognition for his own views on this point, Dr. Kidd (p. 8) deprecates the idea that they militate seriously against the merits of Weismann's theory as a whole. It may be added that the language in which this tribute to a great thinker is couched would have been more elegant had the author avoided the triple use of the word "which" in a single sentence. R. L.

Foundations of Botany. By Joseph Y. Bergen, A.M. Pp. x + 257. (Boston, U.S.A.: Ginn and Co., 1901.)

THIS book is intended, or at least so we gather from the preface, to provide a year's work in an advanced school class. Much of the matter is to be commended, and some of the new figures are admirable. From this side the Atlantic one can only regard with envy the amount of energy expendable in American schools if a work of this proportion and scope is really suited to their possible requirements; for the book covers a wide range of subjects, and will make no small demands on the time of the student who aims at mastering its contents. The author clearly intends that the work shall be grappled with thoroughly, and from the concrete and practical side. He gives directions for laboratory work, and suggests problems to be solved by observation and experiment. These are incorporated in the text as appendices to the chapters, after the prevailing fashion in modern American text-books. It may, perhaps, be questioned whether the book might not be improved by the separation of the purely systematic portion into a volume by itself.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Exploration of the Atmosphere over the Ocean.

THE experiment of flying kites in calm weather from the deck of a moving tug-boat, which was mentioned in NATURE of September 5 (p. 453), was continued by my assistant, Mr. Sweetland, and myself on a steamship that performed the voyage from Boston to Liverpool between August 28 and September 5. Flights were made on five days, the greatest height reached by the meteorograph being one-third of a mile, and the records of barometric pressure, air-temperature, relative humidity and wind-velocity, which are probably the first to be obtained above the North Atlantic, were shown to Section E of the British Association at Glasgow.

These experiments demonstrate conclusively that, with a steamer that can be manœuvred at will, kites can be flown at sea in almost all weather conditions, and, consequently, a most important field is opened for their use in meteorological researches, especially in the tropics, where the conditions existing above the trade-winds are imperfectly known. It is to be hoped, therefore, that such an investigation will be undertaken either by the Government or by private enterprise, and I am now endeavouring to bring this about. A. LAWRENCE ROTCH.

A Curious Flame.

THE kind of phenomenon described by Mr. Garbutt (p. 649) is frequently to be met with in "washed-out" flames, that is, in flames which are diluted to the point of extinction. In such cases the velocity of inflammation is so low that flame cannot propagate itself against the stream of gas. If the current of gas be baffled by an obstacle, then a flame may originate in the "slack waters" round the obstacle. No doubt the temperature of the obstacle is of some importance if the object be small, since rapid withdrawal of heat at any point of a gaseous current is a hindrance to the development of flame at that point. But it will be found that in the experiment described by Mr. Garbutt a flame may be obtained by opposing a large baffling surface of even an enduringly cold body such as a 56-pound weight. In this case a very large portion of the gaseous mixture is made stationary and the cooling down does not affect more than a small film next the metal. A kindred phenomenon is described in NATURE (vol. xlix. p. 86).

The flame obtained when a Bunsen lamp is lighted both at the bottom and the top of the tube is very feeble, and large tracts of it may be extinguished by holding in it beads of volatile salts. ARTHUR SMITHELLS.

November 4.

WITH regard to the flame described by Mr. Garbutt in your issue of October 31, I would suggest the following explanation, which, however, I have not as yet quite proved.

The products of the partial combustion at the bottom of the

Bunsen tube will, in this case, burn with the aid of external heat; but not without some such assistance, because the heat of combustion is so much absorbed by the diluting gases that the temperature of ignition would not otherwise be maintained.

The experiment reminds one of the burning of ammonia, and of a coal-gas flame rendered non-luminous by the admission of steam.

A consideration of Prof. Smithells' method of cone separation by a glass rod (*vide* NATURE, November 1892) might lead to the suspicion that the obstruction of the rod played some part in the phenomenon, but the above explanation is supported by the fact that the copper wire which, when cold, extinguishes a candle flame, does not, when warm, do so.

HERBERT KING.

The School, Wolverhampton, November 2.

The Colours of Guillemots' Eggs.

I AM glad to see that my friend Captain Barrett-Hamilton has written on the above subject, though it seems inconceivable to him that "the beautiful varieties of colouring must help each bird to distinguish her egg from others lying near until they all become stained and soiled." The quotation is from "The Birds of Ireland" (p. 364), in which I put forward, as an opinion, the conclusion that I have been led to after many a day spent in climbing among breeding guillemots.

Discussion of such opinions is to be welcomed, but they must be tested by close observation of the birds and their ways; and the guillemot finding its own egg among many is not the same thing as an animal finding its young, which has voice, smell, movement and expression, nor has the guillemot a nest to find.

It is asked, "Why should each guillemot be provided with a conspicuous private egg-pattern when other sea-birds, her neighbours, have to find their homes without such aid?"

Well, let anyone look down on a guillemot-ledge the last week in May, before the birds have begun to sit close, and he will be struck by the fact that each is provided with a conspicuous egg-pattern, the green eggs contrasting with the white ones and those heavily blotched with the streaked ones; and this is most obvious, even at some distance. I know no other eggs that show such vivid contrasts.

Does this contrast supply any want that the guillemot may have above other birds to enable it to find its egg? Her neighbours, my friend remarks, find their homes without such aid. But then each has her "home." The gulls and cormorants have their nests. Each puffin has its burrow. The razorbills lay much more in separate nooks than guillemots, but still they approach nearest to them both in the nature of their breeding places and in the varieties of egg-colouring. But guillemots lay and sit in packs, often touching one another, on open surfaces of rock (see the plate, "Birds of Ireland," facing p. 362). At first the eggs are often left uncovered and other guillemots alight, lay beside them, and they roll more or less. Must not the special colouring greatly enable the parent bird to find her egg while this is going on? Why should we deny her intelligence in a matter that concerns her, even though other birds are satisfied if they know the way to their nests and do not seem to distinguish whether the eggs in them are their own or not. Thus the cuckoo's egg is unquestioningly accepted by the foster-mother.

It is objected that my suggestion about the colour helping guillemots to distinguish their eggs is disproved by the subsequent admission that they all become stained and soiled as incubation advances; but at that stage each bird clings to her treasure and never leaves it, unless her mate relieves her (a point which needs proof).

The colouring of the eggs of this species is not protective, for it makes them gaudy. It is peculiar, and why should it not be useful during laying-time considering the very peculiar conditions under which guillemots breed? They sometimes come down with a thump among others which are hatching, they sometimes fight, they are awkward on their feet; eggs are not only moved, but many are thrown down, broken or lost in pools.

I wish some ornithologist would contrast from observation the guillemots' colonies on surfaces of rock with those of other birds that breed in packs without nests. Penguins appear to lay on earth and leave lanes between the nesting-places on which the birds travel on foot. That being so, their eggs would not be in such danger of being rolled about.

Cappagh, co. Waterford. R. J. USSHER.

THE TERCENTENARY OF TYCHO BRAHE'S DEATH.[1]

ON October 24, 300 years had elapsed since Tycho Brahe died at Prague, expressing in his last moments the hope that he might not appear to have lived in vain. When saying this he doubtless did not fear that the work he had accomplished might not turn out to be of permanent value, but merely regretted that the great goal he had looked forward to from his early youth, the complete reformation of astronomy, had not yet been fully reached. Could he have foreseen how brilliantly Kepler, who stood at his deathbed, was to complete the work, Tycho would have had no fear as to the lasting nature of his reputation.

It is difficult nowadays to realise that only a little more than 300 years ago it was not a self-evident proposition that the science of astronomy could only be firmly established by observing the heavens systematically year after year, and not merely by taking an odd observation now and then. And yet this does not appear to have occurred to anybody before Tycho, as even Copernicus records very few observations taken during his long life, so that the values of most astronomical quantities had still to be borrowed from Ptolemy. But in August 1563 the young Danish noble, then a student at the University of Leipzig, only sixteen years of age, commenced the series of observations which he carried on, with few interruptions, till the end of his life, thirty-eight years later. The instruments he used at first were crude enough, but already at that time the future reformer of practical astronomy was aware that a very inferior instrument may produce good work if all sources of possible errors are investigated and corresponding corrections are applied to the results of the observations. It is also worth noticing that the planets almost from the beginning claimed his undivided attention, so that the youthful observer had perceived that the existing planetary tables could only be improved if the computed places of the planets were systematically compared with observed places and the errors of the tables thus brought to light. Thanks to the great liberality of King Frederic II. of Denmark, Tycho was afterwards able for more than twenty years, with a multitude of instruments of improved construction and assisted by a number of pupils, to follow the motions of the sun, moon and planets, while he at the same time, by his observations of a thousand fixed stars, gave to the world a catalogue of accurate positions of these bodies which took the place of the old catalogue of Ptolemy and held its own for more than a hundred years, until the use of telescopes and clocks of precision enabled Flamsteed to produce much better star places.

That Kepler made use of Tycho Brahe's observations to find the laws which govern the planetary motions and thereby to free the Copernican system from the excentric circles and epicycles which it had taken over from the Ptolemean system is too well known to require repetition here. But Tycho did a great deal more than merely amassing materials for his successor. Not only was he the first observer who did not assume his instruments to be faultless but who studied their errors of construction, but he was also the first to investigate refraction and to attempt to correct his observations for it, and he succeeded in improving his instruments so much that it is difficult to see how a much greater accuracy could have been attained by succeeding generations, if the telescope had not been invented a few years after his death and if the application of the pendulum to clocks had not simplified many methods of observing. And Tycho was able to deduce many important results from his own observations. By showing that the comets

[1] "Tychonis Brahe Dani die xxiv Octobris A.D. MDCI defuncti operum primitias De Nova Stella summi civis memor denuo edidit Regia Societas Scientiarum Danica. Hauniæ, die xxiv Octobris A.D. MDCCCCI." Pp. 16 + 54 ff. + pp. 30; 2 plates.

observed by him had at most a very small parallax he proved that they were celestial bodies and not mere phenomena in the earth's atmosphere. Important as this discovery was, it is quite eclipsed by the splendour of Tycho's discoveries with regard to the motion of the moon. The ancients knew that the moon's orbit forms an angle of about 5° with the ecliptic, that the two points of intersection (the nodes) travel round the ecliptic in the direction from east to west in about nineteen years, also hat the earth is not at the centre of the lunar orbit, and hat the line of apsides completes a revolution (from west to east) in less than nine years. The great perturbation in longitude now known as the evection, by which the place of the moon may be put forward or backward as much as 1° 16′, was also known, having been dimly perceived by Hipparchus and clearly demonstrated by Ptolemy. But since his time no advance had been made (Sédillot's assertion that Abul Wefa discovered the variation has been clearly and finally disproved). The accurate and long-continued observations of Tycho Brahe revealed the existence of another inequality in longitude, known as the variation, which affects the place of the moon to the extent of 40′, by which amount the moon is ahead of her mean place about three and a half days after new and full moon, and as much behind it about three and a half days after the first and last quarters. He also found the annual equation or the lengthening of the moon's period of revolution in winter and its shortening in summer. Finally, Tycho discovered the variation of the inclination of the lunar orbit and the irregularity of the motion of the nodes. After this series of brilliant successes he cannot have doubted that his observations were destined to reveal the mysteries of planetary motion, and already in 1591 he had commenced to suspect the existence of unknown complications in the motion of Mars, which he afterwards alluded to in a letter to Kepler in 1598, in which he stated that the epicycle of Mars appeared to vary in size. Preparations had already been made for commencing the discussion of the observations of the planets, when an early death closed the life-work of Tycho and obliged him to leave the completion of it to Kepler.

The 300th anniversary of Tycho Brahe's death has been celebrated in his native land by a festive meeting of the Academy of Science at which the venerable King Christian was present, and at which orations were delivered setting forth the importance of Tycho's scientific work. At Prague, where he died, the monument over his recently restored tomb in the Teyn Church was again unveiled, and the interest which the citizens of Prague have always shown in the illustrious exile was manifested in various ways. But though Tycho towards the end of his life felt himself neglected in Denmark and left the country in order to enjoy the society of learned and congenial minds elsewhere, he never forgot the land of his ancestors and his birth; and on the titles of his last writings, as on his first, he describes himself as "Tycho Brahe Danus."

The Copenhagen Academy has chosen a very fitting way of doing honour to the memory of the greatest scientific man Denmark has produced by publishing a facsimile reprint of his earliest publication, "De nova stella" (1573). Tycho's four principal works are found in all great libraries and are not unfrequently met with in the lists of second-hand booksellers. But the book on the splendid new star which appeared in Cassiopeia in November 1572 is so extremely scarce that not a single historian of astronomy had ever seen it or even been able to give the title correctly until the writer of these lines gave an account of it in 1890. Tycho says himself that not many copies were printed and only a few were sent abroad, for which reason he afterwards reprinted the more important parts of it in his larger work, "Astronomiæ Instauratæ Progymnasmata," on which he was engaged during the last fourteen years of his life and which was published after his death. But the whole of the original book, as it left the hand of the young author, is of great historical interest, and we are glad to see the fine reprint now issued, as the star of 1572 was so intimately connected with the progress of Tycho's work.

In a short Latin preface and a Danish postscript of thirty pages, M. Pechüle, of the Copenhagen Observatory, has given a short summary of the origin and contents of the book. Tycho's manuscript was an astronomical, astrological and meteorological almanac for the year 1573, in which he, after a lengthy introduction (to the almanac proper), had inserted his essay on the new star, another on the lunar eclipse of December 1573 and a poem to Urania. After a good deal of persuasion by several friends, Tycho allowed the book to be printed in the spring of 1573, omitting, however, the main part of the almanac. It contains 53 ff, and has now been exactly reproduced in facsimile, but it has been collated with a MS. copy partly written in Tycho's own hand and preserved in the Imperial library at Vienna, in which way a few corrigenda were noticed which are given at the end of the reprint. The book, which is beautifully got up, also contains a specimen of Tycho's handwriting and a copy of a very fine portrait, drawn with pen and ink, found in the Royal collection of engravings at Copenhagen and by some ascribed to the Dutch engraver Goltzius, by others to the painter Gemperlin of Augsburg, who came to Denmark with Tycho in 1575 and afterwards painted the well-known portrait on his mural quadrant. To anyone acquainted with the contemporary literature on the new star and on comets this book will be of great interest, as it gives a very sober account of the startling celestial phenomenon which had given rise to a host of more or less worthless pamphlets and books, and shows that the want of parallax and motion proves the star to belong to the region of the fixed stars. At the same time, it is interesting to see that the author, who was destined afterwards to give the death-blow to the Aristotelean idea of the atmospheric origin of comets, was still a believer in this doctrine when he wrote his first book, but also that he was already then thoroughly aware that the great desideratum of astronomy was an extensive series of observations which he hoped to be able to supply if health permitted and the necessary means were granted him.

Scania, the province east of the Sound, where Tycho was born, and the little island of Hveen, on which his observatory stood, formed parts of the kingdom of Denmark from before the dawn of history and till 1658, when they were torn from the country which had not sufficiently valued him and incorporated in Sweden. It is therefore natural that the recent anniversary of his death also attracted attention in Sweden, and in honour of the day the Physiographic Society of Lund has published a *Festskrift* (20 pp., 4to., with three plates), in which Prof. Charlier, of Lund, gives an account of the recent exploration of the scanty remains of Tycho's buildings on the island. The foundations of Uraniburg were laid bare, as also the floors of the half-subterranean observatory (Stellæburgum (Stjerneborg), but scarcely anything was found more than what the clergyman Ekdahl unearthed in 1823. It has repeatedly, in 1823, in 1868 after the examination of the site by d'Arrest, and now again on the present occasion, been pointed out that "something ought to be done" to protect the ruins from wind and weather, and we may add from relic-hunters also. If this was desirable formerly, when Hveen was a lonely place to which nobody ever went, it has become infinitely more important now, as the island seems to have become the common resort of Sunday trippers from both shores of the Sound, and it would certainly be safer to cover up the foundations again than to leave them unprotected. It has recently been suggested that the observatory might easily be rebuilt from Tycho's detailed and

illustrated description and on the existing foundations and floors of the crypts, and no doubt this would be quite possible. But we confess we should prefer to see a large shed erected over the few stones that are left so that these venerable ruins could remain undisturbed. Most people would prefer looking at the ruins of Kenilworth Castle to walking through a sham castle erected on them and absorbing them. J. L. E. DREYER.

CELEBRATION AT PRAGUE.

Representatives of Bohemian science have recently shown that they delight to remember that Tycho Brahe, the great pioneer of modern observational astronomy, spent the last two years of his scientific activity in the capital of the Bohemian kingdom at a time when, as a seat of the Imperial Court of Rudolph II., the city was one of the most prominent centres of western European culture. It was at Prague that Tycho (Danish, Tyge) Brahe died on October 24, 1601.

The municipal council of Prague took part in the recent celebration, which excited much interest and received a large share of attention in the daily Press.

We cannot give here a detailed account of the scientific career of the great astronomer, but an outline will be of interest. Frederic II. of Denmark gave Tycho means for building the splendid observatory of Uraniburg, but after the death of his royal supporter Tycho was obliged to leave Denmark and his observatory, together with its valuable astronomical instruments.

Tycho went to his friend Count Rantzau at Wandsbeck in 1597 and two years later to the Court of the Emperor Rudolph II. at Prague. But the life at this Court was much too distracting for a scientific worker like Tycho, so he removed to the Imperial castle of New Benatky, where he founded an astronomical observatory. The brass-wire line on the floor, representing the meridian, still exists and is shown as a relic of the observatory. There was also a chemical laboratory, in which Tycho worked.

In the year 1600 Tycho Brahe, at the request of the Emperor, again returned to Prague, where, near the Royal Castle on the ground belonging to Curtius, arrangements were made for building an observatory surpassing even that of Uraniburg in character.

Meanwhile a house, "At the Golden Griffin," was provided for him and his family; and his library, together with his twenty-eight astronomical instruments, was removed to the summer castle of Belvedere, which is named after Tycho even now. Some time afterwards his observatory was removed to the ground of Curtius, where the Czernin barracks are now standing. Here he was assisted in his work by the young mathematician Kepler, who was called by the Emperor to the capital of Bohemia "quoad calculum."

While Tycho was in the midst of his scientific activity he was seized by a sudden illness and after eleven days he died. He was buried in the Teyn Church, and at his grave the learned Bohemian Dr. Jesenius delivered an impressive Latin oration in which he described Tycho's scientific merits and noble character.

The celebration of the 300th anniversary of Tycho's death began at Prague on October 18, where, at a special meeting of the Bohemian Academy of Science, Art and Literature, Prof. Gruss read an address on Tycho's life and scientific influence.

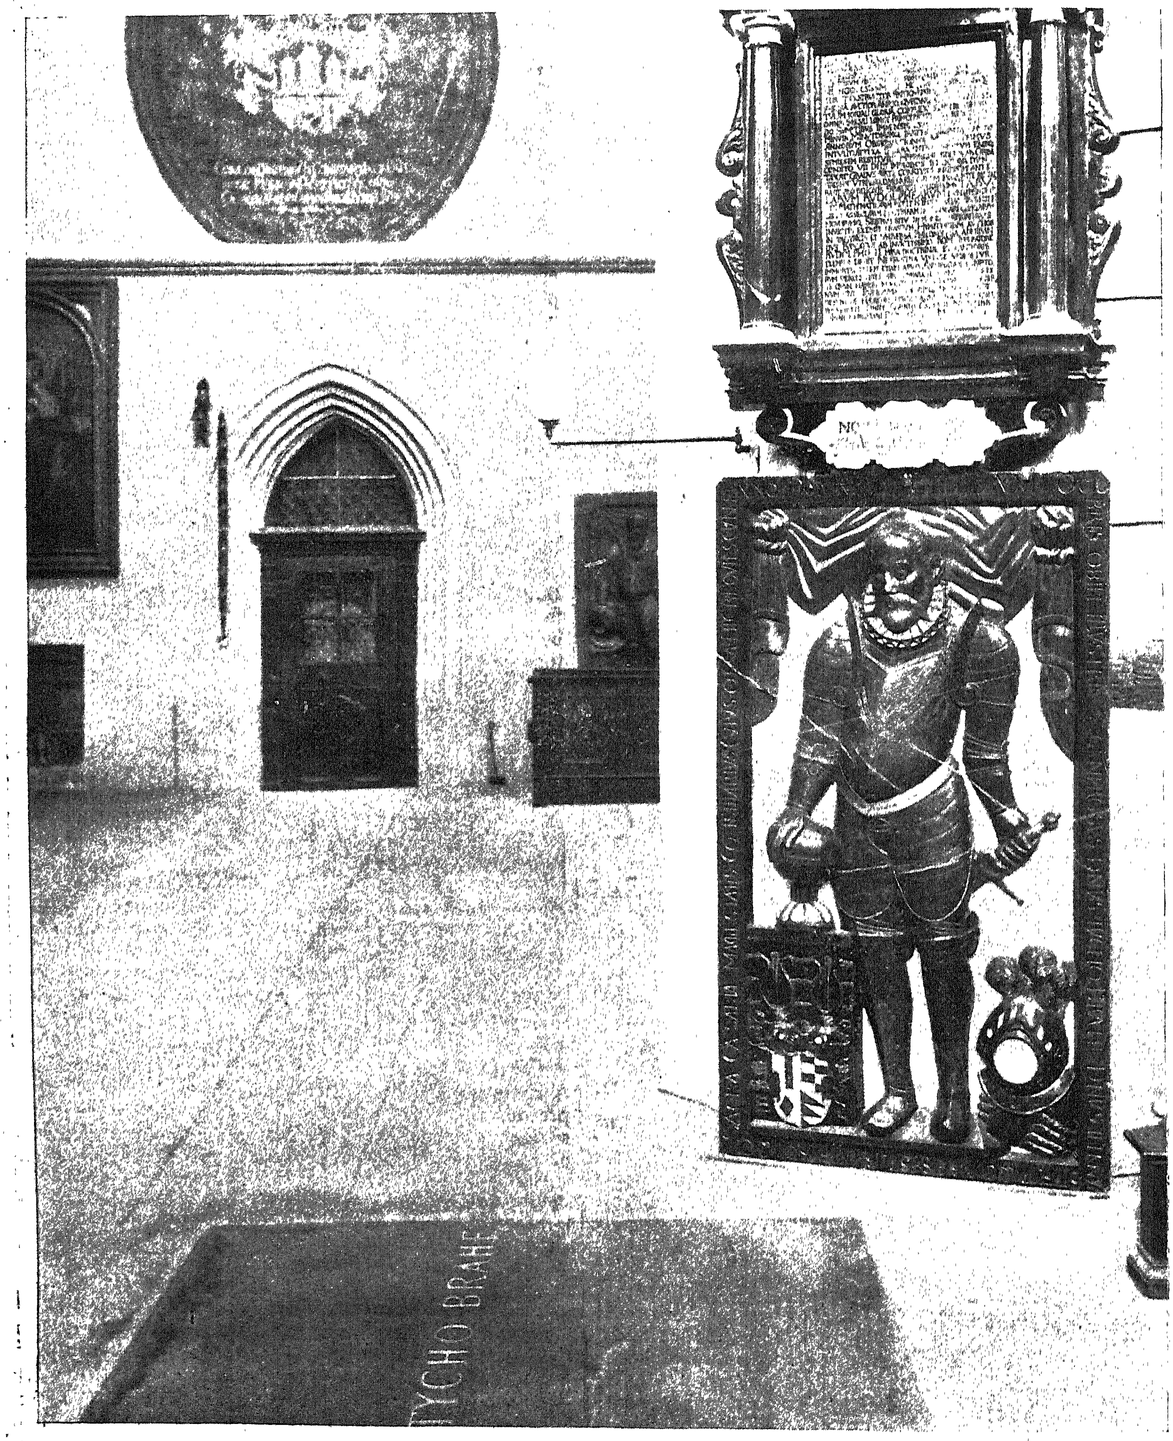
The Royal Bohemian Society of Science celebrated the tercentenary on October 24. In one of the ancient meeting-rooms of the Prague Town Hall an exhibition was held of several Tychonian relics. There was Tycho's magnificent album which was presented by him to his son and is a treasure of antique book-binding; the manuscript, "Triangulorum Planorum et Sphæricorum Praxis Mathematica,"; a manuscript, "Tychonis Brahe Ottonidis (his father's name) Tabulæ Sinuum, 1682"; the memorandum book of Siebold Plan, with an inscription: "Plures sapiunt palato quam cerebro, Tycho Brahe scripsit Uraniburgi, Anno 1591." From Tycho's printed works were exhibited, a copy of Ptolemy's "Almagest," with Tycho's handwriting of 1560; a copy of Copernicus's "De Revolutionibus Orbium Cœlestium Libri VI.," with Tycho's margin notes; a copy of "Tychonis Brahe Astronomiæ Instauratæ Mecanica, Wandesbergi, Anno MDIIC.," which contains Tycho's signature and a dedication to his friend Baron ab Hasenburg, a book containing *inter alia* extremely interesting coloured pictures of the Uraniburg and of a series of Tycho's astronomical instruments. Several other books from Tycho's library bearing dedications to him were also exhibited. All these objects are described in Prof. Studnička's work, "Prager Tychoniana," of which a notice has appeared in NATURE (vol. lxiii. p. 206). There was also exhibited Tycho's Latin poem on the title-leaf of the book, "Prutænicæ Tabulæ Cœlestium Motuum Autore Erasmo Reinholdo"; and a celestial globe made by Tycho's pupil, Willem Iansoon Blaev, in 1603, and containing the positions of fundamental stars as determined by Tycho. Many photographs of Tychoniana were exhibited; some of them, showing the present state of Uraniburg after recent excavations, were contributed by Prof. Thiele. The books and the globe lent for exhibition were from the monastery of Strahov, the Royal Bohemian Museum, and the Imperial Library of the University.

Among those who attended the celebration were Dr. Thiele, professor of astronomy in the University of Copenhagen and rector of the latter, as a representative of the University and of the Danish Academy of Sciences, with his son and assistant, Holger Thiele; Mr. Harald Mortensen, of Copenhagen; and a great number of representatives of Bohemian science. After visiting the exhibition, the representatives went to the Town Hall, where they were received and greeted by the Mayor of Prague. Prof. Studnička then gave an address of the life and work of Tycho Brahe. The meeting was brought to a close by a few historical remarks by Prof. Tomek, the distinguished historian of the city of Prague and president of the Royal Society of Bohemia.

After this a visit was made to Tycho's tomb and monument in the Teyn Church, opposite the Town Hall. It must be remarked here that this church was partly destroyed by fire in 1675 and that its pavement was restored in 1721. It was therefore doubtful whether Tycho's remains would be found there, especially as, after the battle on the White Berg in 1620, the Teyn Church became a Catholic one and the bodies of persons who had held other beliefs were removed. The municipality of Prague, in view of the anniversary, had this question fully investigated by Profs. Schrutz and Matiegka, and it was found that the brick vault of the tomb had been broken during the catastrophes of the seventeenth and eighteenth centuries and that some earth had fallen in. Two bodies were, however, brought out with the greatest care, and it was recognised by many signs, such as the form of the moustache and the fact that a part of the nose had been cut off and replaced by one of metal (chiefly copper), that the skull undoubtedly belonged to Tycho, whose nose was cut off in a duel in 1566, so that he afterwards wore an artificial nose of metal.

The tomb was put in good order and the remains of Tycho and his wife were placed in a metal coffin and again buried. The grave is covered by a large marble plate bearing the inscription, "Tycho Brahe." The tomb and epitaph are represented in the accompanying reproduction of a photograph. As it appears that one of the authors of the inscription on the epitaph was Kepler, we give it here in its full length:—

"Esse potius quam videri.
Illustris et generosus Dominus Tycho Brahe, Danus, Dominus in Knudstrup, arcis Uraniburgi in insula quissima nobilitate clarus, suo auctior animo, quæcunque cœlo continentur, immortali gloria complexus, Astronomorum omnis sæculi longe princeps, totius orbis



Tomb, Tombstone and Epitaph of Tycho Brahe at Prague.

Hellesponti Danici Huenna fundator, instrumentorum astronomicorum qualia nec ante sol vidit, ingeniosissimus idemque liberalissimus inventor et exstructor, anticommodo sumptibus immensis, exactissimas intra minuta minutorumque partes, triginta amplius annorum observationes mundo primus intulit; affixa sidera intra minutum

ejusque semissem restituit: Hipparchi solius ab orbe condito vel diis improbos in octava duntaxat gradus parte conatus longissime antegressus: utriusque luminaris cursum exquisite restauravit, pro reliquis erraticis solidissima *tabularum Rudolphaearum* fundamenta jecit: Mathematicarum rerum peritis inveteratam Aristotelis et asseclarum doctrinam de sublunari cometarum novorumque siderum situ, demonstrationibus invictis exemit: novarum hypothesium autor; in Stagyricis et universa philosophia admirandus; evocatus ab invictissimo Romano imperatore *Rudolpho Secundo*, mira doctrinæ et candoris exempla dedit; ne frustra vixisse videretur, immortalitatem, etiam apud Antipodas scriptorum perennitate sibi comparavit; planeque qualis esse quam haberi maluit, nunc vita functus æternum vivit.

Ejus exuvias uxorisque triennio post defunctæ heredes liberi sacro hoc loco composuerunt. Obiit quarto kalend. Novembris anni Christiani Dionysiaci MDCI ætatis suæ LV.

Non fasces, nec opes, sola artis sceptra perennant." Around the tombstone bearing Tycho's likeness we read: "Anno Domini MDCI die XXIV Octobris obiit illustris et generosus Dominus Tycho Brahe, Dominus in Knudstrup et Præses Uraniburgi et sacræ Cæsareæ Majestatis Consiliarius, Cujus ossa hic requiescunt."

When the visit to Tycho's tomb took place, the Mayor of Prague laid a beautiful wreath upon the tomb which bore the inscription upon ribbons in national colours, "To the great philosopher—the Royal Capital of Prague." Other wreaths bore the inscriptions, "Universitas Hafniensis," "Societas regia scientiarum Danica," "Fra Danske Studenter." There were also wreaths from Prof. Šafařík, the Observatory of Prague, and many others from literary and scientific societies.

The visitors afterwards proceeded to a house on the "Fruit Market," where a memorial tablet of marble was placed stating that Kepler lived there from 1604–1607. In the afternoon the Belvedere of Tycho Brahe was visited and a name "Tycho Street" was given to a new street opposite it. The long row of carriages bearing the numerous visitors then proceeded to a quiet street near the now abandoned Royal Castle, and the house "At the Golden Griffin" was shown, having in front a marble tablet stating that Tycho lived there in 1600 and 1601. Finally, the place was visited where Tycho's last observatory formerly stood and where a new street, bearing the name of Kepler, is now situated.

In this way was celebrated the memory of the great astronomer whose work marks a great epoch in that science, and from whose observations his friend and colleague Kepler calculated his well-known laws.

BOHUSLAV BRAUNER.

CELEBRATIONS IN DENMARK AND SWEDEN.

In Copenhagen the Society of Science celebrated the tercentenary of Tycho Brahe's death in the presence of the King and Royal family and all the members of the Society. The meeting was opened with a short address by the president of the Society, Prof. Jul. Thomsen, who announced that Dr. J. L. E. Dreyer, who was born in Denmark, had had the order of Knight of the Dannebrog conferred upon him by the King. Prof. Fridericia gave a lecture on the personality of Tycho Brahe. He pointed out his scientific enthusiasm and his accurate observations, and showed how towards the close of his life he neglected the mystical side of astrology and regarded astronomy more from the physical point of view. The astronomer's statue in the grounds of the Copenhagen Observatory was decked with wreaths and flowers.

At the University of Lund a bust of Tycho Brahe was unveiled. The Stockholm Academy of Science celebrated the event by a memorial festival in the presence of Prince Eugen and several of the ministers, when speeches were delivered by President Odhner and Prof. Dunér.

STUDIES ON THE ETHNOGRAPHY OF THE NORTH QUEENSLAND ABORIGINES.[1]

ANTHROPOLOGISTS so fully recognised the value of Dr. Walter E. Roth's "Ethnological Studies among the North-West-Central Queensland Aboriginals" that there was considerable satisfaction when the news arrived a year or two ago of his appointment as Northern Protector of Aboriginals in Queensland. We now have the pleasure of receiving two *Bulletins* on North Queensland ethnography, which are the first-fruits of that able investigator's researches in his new sphere, and at the same time we must thank and compliment the Home Secretary's Department in Brisbane for issuing these *Bulletins*, especially as we are promised two or three similar *Bulletins* annually. Dr. Roth expresses his deep indebtedness to the Hon. J. F. G. Foxton for all the kindly encouragement invariably received from him during the prosecution of his scientific labours, and it is due to his wishes, as ministerial head of the Department, that these researches of Dr. Roth's are now being made available to the public. Dr. Roth has anticipated the thanks which anthropologists at home would like to offer to this public-spirited Minister. Publications such as these will do something towards reducing that ignorance of our native races which is largely due to the apathy of our Government as a whole.

The first *Bulletin* consists of an essay by Dr. Roth on "String, and other Forms of Strand: Basketry-, Woven bag- and Net-work." The animal and vegetable products of which strings are made are enumerated, and Mr. F. M. Bailey, the Colonial botanist, has identified the plants from which textiles are made which have been collected by Dr. Roth. The method of making string, including the manufacture of human-hair twine, is fully described and illustrated. Dr. Roth gives in his short direct style accounts of the procedures in which string and other forms of strand are employed. His classification of the processes of construction of basketry, woven bags and network will prove of considerable value to those who have to describe similar textiles from other countries. His explanations are illustrated by nearly a hundred clear diagrams drawn by the author and contained in nineteen plates.

The second *Bulletin* is devoted to the structure of the Koko-Yimidir language, in which Dr. Roth has had the invaluable cooperation of the Revs. G. H. Schwarz and W. Poland, Lutheran missionaries at Cape Bedford Mission Station. This language is spoken from the Annan and Endeavour Rivers to the northern side of Cape Flattery. It is noteworthy that this Koko-Yimidir language is the identical one of which Lieutenant Cook took a vocabulary when visiting the Endeavour River in 1770. A table is given of Cook's words with those in use at the present day; the "kanguroo" of the great voyager is still spoken of as *ganguru*. There are many suggestive notes on the language apart from the interest of the language itself.

We have no doubt that the succeeding numbers will be as valuable as those now to hand, and we shall eagerly await the good things which we are sure Dr. Roth has in store for us.

CHARLES MELDRUM.

DR. CHARLES MELDRUM was born at Kirkmichal, Banffshire, in 1821, and died in Edinburgh in August 1901. He was educated at Aberdeen University, and after graduation as Master of Arts he joined the Bombay Education Department. In 1848 he was appointed professor of mathematics in the Royal College

[1] "North Queensland Ethnography." *Bulletin* No. 1, C.A. 11–1901, price 8s.; No. 2, C.A. 22–1901, price 1s. (Brisbane: by Authority, Edmund Gregory, Government Printer, William Street, 1901.)

of Mauritius, and soon thereafter turned his attention to meteorology, of which he continued to the end one of its most ardent students. It was chiefly by his influence and exertions that the Meteorological Society of Mauritius was founded in 1851, he being its first secretary. He was appointed Government Meteorological Observer in 1862 and Director of the Royal Alfred Observatory in 1875; and in recognition of the great public services he had rendered to the colony he was made a member of the Government Council of Mauritius. For his services to science, more particularly to meteorology, his own University of Aberdeen conferred on him the honour of LL.D.; in 1874 he was elected a F.R.S.; and in 1886 he was honoured with a C.M.G.

Meldrum was a man of untiring energy and perseverance, and to this was added the keenest perception of the absolute necessity there was to replace theoretical speculation by accurate observations in all attempted solutions of the problems of meteorology. In carrying on this large and irksome work he soon displayed a genius in devising the methods for obtaining the physical data required for the investigations he took in hand. His self-devotion to the work was unsparing and unremitting to the end.

His first notable contribution to science was in the attractive field of practical meteorology, by which signal service was rendered to the forecasting of storms within the tropics. The data collected for the purpose was of a twofold nature. First, he clearly saw the paramount importance of a statement of the hourly variations through the months of the year of the pressure, temperature, wind and cloud, and to arrive at which he early instituted "Term Day Observations" as part of the systematic work of the Observatory. In a year or two, approximate hourly averages were thus obtained, and, from these averages, deviations were at once apparent from the regular normal hourly march of the pressure, temperature, wind and cloud.

In the second place, a unique and rich collection of maps of the cyclones of the Indian Ocean began to be prepared from the Mauritius observations, combined with observations obtained from ships' logs, on which isobars, isotherms, winds and clouds were entered, thus depicting from strict observations the outstanding features of the cyclones and gales of the Indian Ocean. In a valuable paper read to the British Association at Dundee, it was shown that the gales and hurricanes of the Indian Ocean south of the equator were conveniently grouped into three distinct types: (1) trade-wind gales, in which the wind veers little, these occurring chiefly in the winter months of June, July and August, when the S.W. monsoon prevails north of the equator; (2) the extratropical gales, occurring south of lat. 30°, in which the wind veers or shifts, these storms being somewhat analogous to the storms of north-western Europe and are most frequent and violent from May to August; and (3) the tropical hurricanes, or true cyclones, in which the wind always veers. It was to this last class that Meldrum mainly directed his attention.

A strict and extended inquiry was carried on respecting the relations between the course pursued by individual cyclones and their changing intensity, and the deviations from the normal values of pressure, wind, &c., observed at the Observatory. The inquiry resulted in showing unmistakably (1) that the direction in which the cyclone was from Mauritius could be readily known from the wind; (2) that its distance from Mauritius could be known from the amount of fall of the barometer and the rate of the fall, taken in connection with the variations in humidity, wind and cloud; and (3) that its progressive motion could be known chiefly from the veerings of the wind. These novel conclusions were soon put to practical use in sending to the daily Press prognostics of cyclones which were attended with complete success. This great result was all the greater inasmuch as it showed that what was done at an isolated station in the ocean might equally be done with success at sea.

In 1874 he submitted another important paper to the British Association at Belfast, "The Cyclone and Rainfall Periodicities in connection with the Sun-spot Periodicity," and in several subsequent years he returned to the same subject. He was one of the earliest workers in this attractive department of science, and his contributions, more particularly as regards the rainfall drawn from all climates, were alike remarkable for the enormous labour involved in their preparation and the lucid clearness with which they established and presented the intimate connection subsisting between the sun-spots and the cyclone and rainfall periodicities.

The Observatory of Mauritius stands second to no other Observatory in the world for the excellence of the physical data it has supplied towards the investigation of these periodicities. As regards the prime elements of climate its records afford the requisite data for the last four complete sun-spot periods from 1855 to 1888, and also the annual number of cyclones in the Indian Ocean from 1847 to 1900, or fifty-four years in all. The following table gives a comparison of the periodicities of the rainfall, pressure, temperature and cyclones. The figures for the rainfall, pressure and temperature are given as differences from their annual averages, the differences being "bloxammed" in the usual way.

Year of sunspot period.	I.	II.	III.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.	Average.
Sunspots, 1855–1888	10	5	18	49	90	90	84	63	45	29	20	
Rainfall, inches	−1·3	1·2	−0·4	0·4	−1·2	2·5	3·9	5·5	−1·3	−3·5	−5·5	46·9
Pressure, 1000th of an inch	1	1	3	7	11	−1	−7	−10	−4	−2	3	30·069
Temperature, degrees	0·1	−0·1	−0·3	−0·5	−0·3	0·0	0·2	0·3	0·4	0·3	0·2	73·6
Indian Ocean cyclones, 1847–1900 ...	5	3	5	8	12	10	10	10	8	7	5	8

The result shows an intimate connection between the prime elements of meteorology and the sun-spot variation.

In 1866 Dr. Meldrum visited England, one of the chief objects in view being to obtain a complete set of magnetical and meteorological registering instruments suitable for a first-class observatory. These were received in course, and by the end of 1874 were installed, and at work, in the new Royal Alfred Observatory, of which he was appointed the first director. The results have been published in the Annual Reports since, and in the Report for 1899 Mr. Claxton has begun to give the larger results of the work of this Observatory, beginning with the diurnal variation of the atmospheric pressure deduced from twenty-five years' observations (1875–99), and of some of the other chief elements of climate for shorter terms of years. These results are simply of inestimable value, not only to men of science, but also to navigators.

Some time ago there was added to the regular routine of the Observatory the taking of photographs of the sun when the weather permitted. The number of photographs taken in 1900 was 377; they have been

transmitted to Sir Norman Lockyer, director of the Solar Physics Observatory, South Kensington.

In consideration of the valuable work so minutely and ably carried on at this Observatory in the departments of meteorology, general physics and magnetism, the publication *in extenso* of these daily and hourly observations becomes a question of national importance, in view, especially, of the large results now in course of evolution.

ALEXANDER BUCHAN.

NOTES.

THE presidential address delivered by Mr. Charles Hawksley at the Institution of Civil Engineers on Tuesday was very comprehensive in its scope. Being the first inaugural address delivered at the Institution since the commencement of the new century, the opportunity was taken of giving a retrospect of advances made in the past century in the more prominent branches of civil engineering. At the commencement of the nineteenth century engineering works were comparatively few in number. Railways, steamships, electric telegraphs, telephones, the use of electricity for lighting and motive-power, were all unknown. Lighting by means of coal-gas had only just been introduced, and even the steam-engine was then in a primitive stage. Looking backward, and comparing the condition of things a hundred years ago with the present state, the changes which science and invention have brought about certainly appear remarkable. But it is advisable not to rest satisfied with a complacent view of the progress made. There is a prospect as well as a retrospect, and it is essential to push forward into the new fields of work before they are occupied by other nations. This is the lesson which must be impressed upon the minds of the British people, and used to give their political leaders a sense of responsibility for national welfare in the future. Engineers are not usually inclined to accept the view that action is necessary if we are not to be beaten in the industrial war which is now going on, but Mr. Hawksley acknowledges that "British engineers and manufacturers cannot hope to possess in the twentieth century that practical monopoly which they enjoyed during a considerable part of the nineteenth century." The conditions have changed, and unless our engineers and manufacturers adapt themselves to the new environment they will be superseded by men of other nations more in touch with the times. Mr. Hawksley mentioned in his address the serious difficulties and disadvantages under which British manufacturers are placed by the lack in this country of acknowledged standards. A committee formed to consider the subject in June last decided unanimously that it was desirable to issue standard sections and standard specifications, and the Institution of Civil Engineers has taken the work in hand. Four committees dealing with different branches of industry have been formed and are now at work standardising the various sections used in engineering practice.

THE death is announced of Prof. Ralph Tate, F.L.S., F.G.S., professor of natural science in the University of Adelaide, South Australia. Tate was a naturalist of the old school, with a good knowledge of botany, field zoology and geology. His earliest researches were carried out in the neighbourhood of Belfast, and he published papers on the Lias and Cretaceous rocks in the *Quarterly Journal* of the Geological Society. In 1864 he was appointed museum assistant to that Society, a position which he occupied for about four years. During this period and up to the year 1876 he devoted his attention mainly to the Mollusca and especially to the Gasteropoda of the Lias. In conjunction with Prof. J. F. Blake, the well-known "Yorkshire Lias" was published in 1876. In that year Tate left England for the University of Adelaide, and henceforth his labours were devoted to the geology and natural history of Australia. In 1893 he was elected president of the Australian Association for the Advancement of Science. His later contributions to science dealt chiefly with the Tertiary Mollusca of Australia.

DR. A. H. BENNETT, only son of the late Prof. John Hughes Bennett, of Edinburgh, and author of several works relating to diseases of the nervous system, died on Friday last at the age of fifty-three.

AT the ordinary quarterly comitia of the Royal College of Physicians, held last week, it was resolved to send delegates to the congress on medicine to be held at Cairo in December 1902, and also to the International Congress in Medicine, to be held in Madrid in April 1903. A proposal from Mrs. FitzPatrick to found a lectureship in the college, accompanied by a draft for 2000*l.*, was accepted, and it was resolved to send the following expression of thanks on vellum and sealed with the College seal:—"The President and Fellows of the Royal College of Physicians of London, in comitia assembled, tender their cordial thanks to Mrs. FitzPatrick for her munificent gift of 2000*l.* for the purpose of endowing a lectureship on the history of medicine in memory of her late husband, Dr. Thomas FitzPatrick, a member of the college; they gratefully accept the same and undertake faithfully to administer the trust she has committed to them."

IT is stated by the Berlin correspondent of the *Times* that Prof. Paul Ehrlich, of Frankfurt-on-the-Main, has been enabled to devote himself to a special study of the disease of cancer in consequence of a bequest of the interest for three years of a sum of 500,000 marks dedicated to this purpose by a Frankfurt banker, the late Herr Theodor Stern. Other sums contributed by private individuals will bring up the amount to be devoted to this special investigation of cancer by Dr. Ehrlich to 40,000 marks, or 2000*l.* a year. In Berlin there exists a special committee for the investigation of cancer, which studies pathological accounts of cases and collects statistics and medical literature on this subject. Prof. von Leyden is at the head of the committee, and Prof. von Kirchner, of the medical department of the Ministry of Public Instruction, is one of its members.

MR. NORTHCOTE THOMAS has been appointed organising secretary to the Society for Psychical Research.

THE biennial dinner of the Physical Society of London will be held at the Hotel Cecil on Friday, November 15.

THE Christmas course of six lectures to young people, at the Royal Institution, will this year be delivered by Prof. J. A. Fleming, F.R.S. The subject will be "Waves and Ripples in Water, Air and Æther," and the first lecture will be delivered on Saturday, December 28.

THE new session of the Institution of Electrical Engineers will be opened on Thursday, November 21, when the premiums awarded for papers read or published during the session 1900–1901 will be presented, and the president, Mr. W. Langdon, will deliver his inaugural address.

THE Siberia-Oriental Section of the Russian Imperial Geographical Society will celebrate the fiftieth anniversary of its foundation on November 17/30.

THE scientific committee of the Aëro Club of Paris has decided to award the Deutsch prize of 100,000f. to M. Santos Dumont.

AN illustrated public lecture on Jamaica was delivered at the Imperial Institute on Monday by Mr. Herbert Thomas, who had resided continuously for the last twenty-five years in the island. In describing the principal products of the island, Mr.

Thomas said that the lamentable decay of the sugar industry could not be more forcibly illustrated than by the fact that whereas at the beginning of the nineteenth century 800 sugar estates had been under cultivation, there are now only 125. Even Jamaica rum is in less demand than formerly, having been largely superseded—even in the island itself—by whisky. On the other hand, the fruit trade of late years has made great strides; its value was 40,000*l*. in 1879 and 635,000*l*. in 1899. Tobacco is a product with a great future in store for it; also cocoa, the cultivation of which has recently largely increased and its quality improved.

THE conviction having arisen in the minds of many members of the American Philosophical Society that the time has come when the interests of useful knowledge in the United States can be greatly promoted by the holding, in addition to the Society's usual fortnightly meetings, of at least one general meeting in each year, the Society has authorised the holding of a general meeting in Easter week of next year, and a committee has been appointed to make the necessary arrangements. Members desiring to present papers, either for themselves or others, are requested to send to the secretaries at as early a date as practicable and not later than February 15, 1902, the titles of the papers, accompanied by a brief abstract, so that they may be duly announced on the programme, which will be issued immediately thereafter and which will give in detail the arrangements for the meeting.

THE "Chemical Society's Memorial Lectures," delivered between 1893 and 1900, have been published in a separate volume, which can be obtained from Messrs. Gurney and Jackson. There are twelve lectures in the volume, most of them important contributions to the history of chemistry and all of interest as descriptions of work to which the progress of modern chemical science is largely indebted. Several of the lectures were reported or abridged in these columns when they were delivered. The twelve chemists whose scientific careers are reviewed in the lectures, now rendered available in a convenient form, are Stas, Kopp, Marignac, Hofmann, Helmholtz, Lothar Meyer, Pasteur, Kekulé, Victor Meyer, Bunsen, Friedel and Nilson.

WE have received from the Home Office a copy of Dr. Le Neve Foster's general report on the minerals raised in the United Kingdom during 1900, and therein we learn that the value of the output, exclusive of the product of shallow quarries, was no less than 135,957,676*l*., or nearly thirty-eight and a half million pounds more than that of 1899. The enormous increase is due partly to the larger quantity of coal produced, the excess being more than five million tons, but it is mainly owing to the higher average price per ton. To coal is due 89 per cent. of the total value of the output of our mines and quarries. Next in importance is iron-ore, the value of which is about four and a quarter million pounds. It is satisfactory to note that gold mining in Wales was carried on with an excellent margin of profit; no less than fourteen thousand ounces of bar gold were obtained, and the value was upwards of fifty-two thousand pounds.

TWO quarterly parts of a catalogue of Polish scientific literature, prepared by the bibliographical committee of the Department of Mathematics and Natural History of the Academy of Science at Cracow, have been received. The catalogue is intended to form a complete current list of Polish publications, commencing with the present year, and including separate works and dissertations, papers in scientific journals, and translations into Polish from other languages. It is also intended as a contribution to the International catalogue of scientific literature now in course of preparation. Each title is given alphabetically in its proper section under the name of the author, and a translation of the Polish title is added in English, French, Latin, German or Italian. The subject classification adopted in each part is as follows:—(A) pure mathematics; (B) mechanics; (C) physics; (D) chemistry; (E) astronomy; (F) meteorology (including terrestrial magnetism); (G) mineralogy (including petrology and crystallography); (H) geology; (J) geography (mathematical and physical); (K) palæontology; (L) general biology; (M) botany; (N) zoology; (O) human anatomy; (P) physical anthropology; (Q) physiology (including experimental psychology, pharmacology and experimental pathology; (R) bacteriology.

THE Report of the Royal Prussian Meteorological Institute for the year 1900 shows that steady progress is being made in the work of the various departments. The newly erected observatory on the Schneekoppe began to work regularly on June 1, 1900. The investigation of the upper air is actively carried on by means of kites, provided with self-recording instruments; on one occasion a height of 4255 metres was reached. The number of meteorological stations now amounts to some 200, in addition to 2200 rainfall stations; more than 1400 stations report thunderstorms and unusual occurrences either directly or monthly by post-cards. The results of the observations are published in annual, monthly and weekly reports, and the staff is encouraged to contribute discussions to various scientific journals.

THE Meteorological Office pilot chart of the North Atlantic and Mediterranean for the month of November shows that during September there was a rapid diminution in the quantity of ice on the western side of the Ocean, the latest report of a berg eastward of Newfoundland being as far back as September 11. In the strait of Belle Isle and eastward to the 50th meridian large and small bergs were still numerous, but they were noted as greatly thinned out since the previous month. Various local features of the Atlantic winds in November are dealt with, and as regards the ocean currents it is pointed out that at this season the Gulf Stream exhibits a decided slackening in the vicinity of Cape Hatteras, where the maximum velocities are reduced from 50 to 80 miles in October to as low as 30 to 45 miles. This, however, would appear to be a local check, for to south and north the rates are but slightly altered. On the African coast, between Capes Blanco and Palmas, a distance of more than 1000 miles, there is a westerly to north-westerly current setting away from the land. Mariners are cautioned as to the dangers from wrecks and derelicts, and particularly near the American coast, some portions of which are studded with sunken wrecks. A similar caution is given as to rollers down the west coast of Africa, which sometimes break with great violence in from nine to three fathoms. A new feature of the chart is the monthly discussion of the paths of barometric depressions affecting the Mediterranean. In November there are three main lanes each having its own influence on the winds experienced. The principal one proceeds from the Bay of Biscay across Corsica to Asia Minor, but another important one enters from the south-westward by the Strait of Gibraltar, or further north, passing across Sardinia and Italy, influencing the weather of the western basin, being the primary cause of the severe northerly and north-westerly gales there experienced. Both series of disturbances exhibit a tendency to lag on nearing Italy. The third group of depressions appears to traverse Algeria and Tunis, to enter the Mediterranean about the Gulf of Kabes, and move eastward across Cyprus.

THE autumn of 1899 was marked in the United States by a great development of the fall army-worm (*Laphygma frugiperda*), which probably was as injurious as any other insect that season, being destructive to a great variety of crops over a large

area. In *Bulletin* No. 29 of the entomological division of the U.S. Agricultural Department, Mr. F. H. Chittenden gives an account of this visitation and also of the life-history of this pest, as well as of the variegated cut-worm. The account of the former is the fullest hitherto published, but the sudden disappearance of the insect as a pest in 1900 prevented observations from being taken to complete its history. It is considered probable that the sudden destruction of this and other insect pests of apparently southern origin is due to peculiar atmospheric and other conditions in the late autumn. When the northern localities are restocked the following season, it appears to be owing to an influx of moths from the south.

WE have received two *Bulletins* (Nos. 28 and 30) from the Entomological Division of the U.S. Department of Agriculture, the one dealing with "Insect Enemies of the Spruce in the North-east" and the other recording some miscellaneous results of the work of the Division. Dr. A. D. Hopkins is the author of the former, while Dr. L. O. Howard and several other writers contribute to the latter. It appears that in New England and adjacent territories the valuable forests of red spruce (*Picea rubens*) have during the greater part of the last century been in a very unhealthy condition, numbers of trees dying over large tracts. The chief cause of the mischief is a beetle, described as a new species under the name of *Dentroctonus piceaperda*. After describing the life-history of this pest, the author suggests various remedies for checking its ravages. The more important contents of the second *Bulletin* include a dissertation on the ravages of the "differential grasshopper" in the Mississippi delta, experiments on insecticide, the carriage of disease by flies, the invasion of the codling moth in Idaho during 1900, and the influence of the weather on insect life in the same year. Mr. F. H. Chittenden, the author of the last-mentioned memoir, previously hazarded the suggestion that certain northern forms would continue to flourish after protracted cold weather, which would probably prove fatal to southern types invading the area under observation, and this prediction has been to a considerable extent verified. Both *Bulletins* are well illustrated, the plates in No. 28 being exceptionally good.

IN No. 8 of the *Bulletin* of the Royal Belgian Academy for the current year, M. Julien Fraipont publishes the first instalment of a re-exploration of the Engihoul cavern, Engis, carried out with the assistance of the "Elizabeth Thompson fund." In this communication the author describes the remains obtained from a bears' resort. These are provisionally assigned to *Ursus arvernensis*, *priscus*, *spelaeus*, *ferox* (=*horribilis*) and *arctus*. From comparison with the skull of a large brown bear from the Asiatic coast of Bering Strait, the author makes the suggestion that all these forms may eventually turn out to be specifically inseparable from *U. arctus*.

IN the October issue of the *American Naturalist* Prof. W. M. Wheeler brings to a close his dissertation on the compound and mixed nests of American ants, to which allusion has been made on two previous occasions in our columns. In his concluding paragraphs the author observes: "Wasmann has shown in detail why it is quite unnecessary to assume the existence of anything beyond instinct and simple intelligence in the ants which form compound and mixed nests. I should even be inclined to place a more moderate estimate than Wasmann on the psychical endowments of these animals. . . . Having arrived at the same conclusion as Wasmann, that there are no evidences of ratiocination in ants, we have reached the limits of our brief inquiry. This conclusion, however, even if it be extended so as to exclude all animals except man from a participation in this faculty, does not imply the admission of a qualitative difference between the human and animal *psyche*."

TO the *American Naturalist* Prof. Bashford Dean communicates some highly interesting notes on living nautili from the strait between the islands of Negros and Cebu in the southern part of the Philippine group. Hearing that these cephalopods were commonly captured by the inhabitants of those islands, Prof. Dean paid a visit to Negros, but as the time of year was not propitious he succeeded in obtaining only a few examples. In June, which is the best season, as many as twenty specimens are occasionally taken in a single fish-trap. These fish-traps, of which examples are figured by the author, are sunk by the fishermen in deep water (from about 225 to 350 fathoms), and the nautili are taken in considerable numbers. Not that they are an object of the fishery, for although their flesh is eaten it is but little esteemed, and the shells have till recently found little sale, although matters are improving in the latter respect. Prof. Dean gives several figures of the shell, with and without the soft parts, and shows how male are distinguishable from female specimens by the form of the aperture. Twenty hours was the longest time a specimen was kept alive. Nautili in this region appear to have a definite breeding-season, during which the author thinks it probable that the natives not unfrequently obtain eggs. Our readers will recall a description of nautilus eggs from New Guinea by Prof. Willey which appeared in our columns in 1897.

THE first part of a new Cryptogamic Flora of Germany, by Dr. W. Migula, has been issued, in connection with Thome' "Flora von Deutschland, Oesterreich, und der Schweiz."

DR. A. TOMMASI has sent us a copy of a memoir on a collection of Triassic fossils from the Valle del Dezzo, Italy, recently published in *Mem. Ist. Lombardo* (vol. xix. pt. 4). The fauna seems most nearly allied to that of St. Cassian; but a number of new species of molluscs and brachiopods are described.

THE October number of *Climate* is mainly devoted to the subject of malaria, and has in it a paper by Sir William MacGregor entitled "Malaria and its Prevention," articles on the malaria question, and the West African climate, also the general outlines of a course of ten health lectures, which, at the suggestion of the Governor, have recently been given to sanitary inspectors, hospital nurses, teachers and others at Lagos.

THE *Proceedings* of the Liverpool Geological Society (vol. ix. part 1, 1901) contain important communications by the late G. H. Morton on the Carboniferous Limestone series of North Wales, and of especial interest is his tabular list of the fossils, showing their range in the various subdivisions and their occurrence in the four districts of Llangollen, Flintshire, Vale of Clwyd and Llandudno, and Menai Strait and Anglesey. In the same publication Messrs. T. Mellard Reade and P. Holland deal with the Green Slates of the Lake District and discuss the subject of slaty cleavage. They maintain that real slaty cleavage is always accompanied by mineral changes in the body of the rock, which not only give the foliaceous character, but supply the necessary cement to bind together the overlapping constituents and convert what was originally mud into a rock possessing the tenacious and economically useful properties of slate.

THE clays and clay industries of Wisconsin form the subject of a memoir, by Dr. E. R. Buckley, which is published by the Wisconsin Geological and Natural History Survey (*Bulletin* No. vii., Economic Series, No. 4, 1901). Following the plan adopted in many American works, the author commences with the origin of clay, and passes on to the composition, classification, properties and behaviour of clays in general before he deals with the clay deposits of Wisconsin. These are both residual and transported, the residual clays being due to the decomposition of granite, greenstone, limestone, shale and other rocks. The transported clays are by far the more extensive, comprising

those of glacial, lacustrine, fluviatile and even wind-borne origin. The author describes the methods of manufacturing brick and drain tile, and then proceeds to record in detail his observations on the clays, and the local modes of working and manufactures in Wisconsin. In appendices he notes the methods employed in the examination of the clays in the field and in the laboratory, and he gives numerous analyses. A map and many other illustrations accompany this work.

MESSRS. JOHN WHELDON & Co. announce the publication of the first volume of the "Botany of the Færöes," edited by Prof. E. Warming. The present volume is occupied by the land and freshwater flora (phanerogamic and cryptogamic); the remaining volume will be devoted to the marine flora, to agriculture and gardening, and to other general subjects.

THE publication of the Kew *Bulletin of Miscellaneous Information* has been resumed, with Nos. 175–177, containing instalments of the Diagnoses Africanæ, Decades Kewenses, New Orchids, and Fungi Exotici. The *Bulletin* records, with regret, the retirement of Mr. George Nicholson from the curatorship of the Gardens, in which post he is succeeded by Mr. Wm. Watson. Mr. Nicholson had devoted himself largely to the extension and improvement of the arboretum, and was compiler of the hand-list of trees and shrubs grown in it.

THE *Journal of Applied Microscopy and Laboratory Methods* (published by the Bausch and Lomb Optical Co., Rochester, N.Y.) for October gives a full description, with photographic illustrations, of the botanical laboratory and the botanical garden of the Tokyo Imperial University, Japan. The University buildings comprise a herbarium, library, laboratories, museum, lecture-room, and rooms for a professor and three assistants. Special facilities are given for the study of bacteriology and fermentation. The curriculum for lectures comprises courses in morphology and physiology, in systematic botany, and in advanced physiology. The laboratory work includes courses in classification, morphology, histology, physiology, and embryology, as well as special research work. It is an important feature of the University curriculum that exclusive specialisation is not encouraged. Students who specialise in botany are required also to take courses in zoology, including histology and embryology, geology, palæontology, mineralogy, physiological chemistry, and bacteriology. There are special courses in the agricultural college of the University in forestry and agriculture. The botanic garden has been established for about two hundred and twenty years, and is about five acres in extent. In the same number of the *Journal of Applied Microscopy* is an account, with photographic illustrations, of the course of study in invertebrate zoology in the marine biological laboratory at Wood's Holl.

MESSRS. JORDAN AND SNYDER continue their valuable review of Japanese fishes in the *Proceedings* of the U.S. Museum, the last part we have received dealing with the so-called cardinal fishes (Apogonidæ). Two new species of the typical genus Apogon are described, while a new generic type receives the name *Telescopias gilberti*.

NOS. 1246 and 1247 of the *Proceedings* of the U.S. Museum contain lists, by Messrs. Robinson and Lyon, of mammals and birds recently collected in La Guaira, Venezuela; while in No. 1248 Dr. Stejneger deals with the reptiles and batrachians of the same locality. No. 1250 of the same serial is devoted to a review of the Atherine fishes of Japan, by Messrs. Jordan and Starks. In No. 1252 Dr. Stejneger describes a new bull-frog from Florida; and in the succeeding part Mr. N. Banks treats of certain spiders and other arachnids from Porto Rico.

THE U.S. Department of Agriculture has sent us Nos. 20 and 21 of the "North American Fauna," the former containing a revision of the typical skunks, by Mr. H. A. Howell, and the latter an account of the natural history of the Queen Charlotte Islands and Cook Inlet, Alaska, by Mr. W. H. Osgood. The chief feature in the first article is the proposed substitution of the name Chincha for the familiar Mephitis. In treating of the Queen Charlotte group Mr. Osgood mentions that although a supposed new species of reindeer has been recently described from Graham Island, it is more than doubtful whether any of those animals inhabit the group.

MESSRS. TOWNSON AND MERCER, of Camomile Street, London, E.C., have prepared a series of standard colour tubes—specially for the use of the wine trades—to which purchasers of sherry or other wine may refer any particular sample. As one of the factors in the sale of wine is a certain colour, it will be seen that if a trustworthy standard is established for comparison considerable expense and inconvenience will be saved. It is claimed that the tubes are absolutely permanent in colour and brightness, having been sterilised and made antiseptic, and, so far as we have been able to test it, the liquid in the hermetically-sealed glass cylinder forwarded to us has undergone no change. There is much to be said in favour of these standard tubes. It is much more trustworthy to refer a purchase to an accepted standard colour than to some tint which one endeavours to carry in the eye, or to a stored sample that may have undergone change. It is evident, however, that the range of colour tubes must be fairly extensive, particularly if they are to cover more than one class of wine; must be permanent in tint and brightness; and must have the approval of the wine trades.

THE brief description of the Hammer-Fennel tacheometer given in our issue of October 17 (p. 598) contains a sentence which Prof. Hammer desires to correct. Referring to the use of the instrument, the reviewer remarked:—"The diagram and mechanical adjustments are so arranged that by multiplying the observed displacement of the line from the zero by 20, the difference of altitude in metres will result, while another displacement multiplied by 100 gives the distance." This is not exactly the case. Prof. Hammer informs us that it is "not the displacements of any lines which have to be multiplied, but the section of the rod or stadia contained between the zero-line (horizontal wire) of the diagram and two other points of the diagram; these two points are indicated automatically in the diagram by raising or dipping the telescope."

A PRACTICAL aid to reasonable instruction in geography is provided by the *Geographical Teacher*, the first number of which has just been published. The new periodical is the organ of the Geographical Association (which exists for the purpose of improving the teaching of geography), and it is edited by Mr. A. W. Andrews and Dr. A. J. Herbertson. Mr. Douglas W. Freshfield, president of the Association, contributes an introduction, in the course of which he says that the aim will be to show that the question which Dr. Jowett once put to him, "Can you teach geography so as to make people think?" can be answered in the affirmative. The contributions to the first number substantiate this opinion. Among the subjects are methods of teaching geography, with their limitations and possibilities, the study of maps, geography of the world, photography as an aid to geography, and school excursions. The journal will be published three times a year by Messrs. George Philip and Son.

A TRANSLATION, by Dr. W. H. Thompson, of Prof. Pawlow's lectures on "The Work of the Digestive Glands," embodying the results of researches which were recently awarded the Nobel Prize of 11,000*l.*, will be published immediately by Messrs. Charles Griffin and Co. This edition will include the later volume, entitled "The Experiment," &c., together with the notes of the most recent researches of Prof. Pawlow.

SEVERAL new editions of scientific books of established reputation have recently been received. The fourteenth edition of Naumann's well-known "Elemente der Mineralogie," edited by Prof. F. Zirkel, has been published by Mr. Engelmann, Leipzig (London: Williams and Norgate). The book stands in the first rank of treatises on mineralogy, and is likely to maintain this position while it is so well kept in touch with scientific progress by revised editions.—A similar standard work is Gray's "Anatomy: Descriptive and Surgical," the fifteenth edition of which, edited by Messrs. T. Pickering Pick and R. Howden, has been published by Messrs. Longmans, Green and Co. The entire work has undergone revision, and the section on embryology has been considerably amplified. The volume will thus secure the attention of students for some time to come.—The third edition of Prof. A. H. Church's "Chemistry of Paints and Painting" has been published by Messrs. Seeley and Co. An elaborate and appreciative review of this book appeared in these columns nearly ten years ago (vol. xlv. p. 243). The plan remains the same as in the first edition, but many slight changes have been made and new pigments, or new varieties of old pigments, are described. In the four last chapters Prof. Church gives "adequate evidence of the instability of several favourite pigments largely used by painters in water-colour during the eighteenth and nineteenth centuries."—Mr. Walter Scott has published the third edition of Mr. Havelock Ellis's book on "The Criminal," which was reviewed in these columns when the first edition appeared (vol. xlii. p. 75, 1890). Since then increasing attention has been given to criminal anthropology, and Mr. Ellis gives a valuable statement of the present position of the subject. His book has been enlarged by more than one hundred pages, and much new material has been examined and summarised.

WE have received a copy of Prof. Letts' report on the scheme of sewage purification for Belfast and its probable effects on the Lough. In this report Prof. Letts first deals in a simple way with the chemical nature of sewage and the various methods of sewage disposal. He then deals with the subject of the vast deposits of sea-lettuce (*Ulva latissima*) which accumulate on the Belfast foreshore and, undergoing decomposition, produce serious nuisance. It is shown that the development of the sea-lettuce, which is extraordinarily rich in nitrogen, is associated with the presence of sewage in sea-water and that it thrives wherever an ordinary sewage effluent escapes into sea-water. Coming next to the proposed method of treating the Belfast sewage by double contact with bacteria beds and the discharge of the resulting effluent into the Lough, Prof. Letts concludes from his experiments that the bacteria beds are dispersers rather than converters of nitrogen, that is to say, they liberate a large proportion of sewage nitrogen in the gaseous form. Hence the effluent from such beds is unlikely to stimulate the growth of the noxious green seaweed, and Prof. Letts considers it probable that the proposed system of sewage treatment will eventually suppress the growth sufficiently to put an end to the existing nuisance. In a series of recommendations appended to his report, Prof. Letts suggests the reclamation of large tracts of foreshore and more systematic removal of the decomposing weed. He thinks it probable that by allowing the sewage effluent to flow into tidal ponds containing sea-water and sea-lettuce the nitrogen content might be reduced almost to the vanishing point. The lettuce could be regularly removed and used advantageously as a manure.

THE additions to the Zoological Society's Gardens during the past week include a White-fronted Capuchin (*Cebus hypoleucus*) from Central America, presented by Mr. G. B. Apostoloff; two Syrian Bulbuls (*Pycnonotus xanthopygos*) from Tayif, Arabia, presented by Mr. G. P. Dovey; a Hocheur Monkey (*Cercopithecus nictitans*, ♀) from West Africa, a Simpae Monkey (*Semnopithecus melalaphus*, ♂) from Sumatra, three Ogilby's Rat Kangaroo (*Bettongia penicillata*) from Australia, a Zebra (*Equus* —— ♂), four Young Lions (*Felis leo*, ♂ ♂ ♂ ♂), a Caracal (*Felis caracal*) from Abyssinia, an Indian Antelope (*Antilope cervicapra*), a Ruddy Ichneumon (*Herpestes smithi*) from India, a Goshawk (*Astur palumbarius*), European; five Smooth-clawed Frogs (*Xenopus laevis*) from Africa, deposited; twelve Changeable Troupials (*Quiscalus versicolor*), six Painted Terrapins (*Chrysemys picta*), two American Box Tortoises (*Cistudo carolina*), a Copperhead (*Ancistrodon contortrix*), two Horrid Rattlesnakes (*Crotalus horridus*) from Pennsylvania, three White-eyebrowed Finches (*Zonotrichia leucophrys*), three Lark Buntings (*Calamospiza bicolor*), three Mexican Quails (*Callipepla squamata*), two Painted Box Terrapins (*Cistudo ornata*), five Poinsett's Lizards (*Sceloporus torquatus*, var. *poinsetti*), ix Lesser Horned Lizards (*Phrynosoma modestum*), a Say's Snake (*Coluber catenifer*, var. *sayi*), a Confluent Rattlesnake (*Crotalus confluentus*), two Testaceous Snakes (*Zamenis flagelliformis*), two Western Diamond Rattlesnakes (*Crotalus atrox*) from Pecos, Texas; two Common Rattlesnakes (*Crotalus durissus*), two Couper's Snakes (*Spilotes corais*, var. *couperi*) from Marion co., Florida, received in exchange.

OUR ASTRONOMICAL COLUMN.

THE PERIOD OF ALGOL.—Prof. S. C. Chandler has made a further investigation of the minor inequalities of the period of Algol. These have probably escaped notice up to the present owing to their being so minute as to be of the same order as the errors of observation.

This later inquiry indicates that the deviations of the observed from calculated times of minima have been periodic, distinct changes occurring in the course of a few months, but it does not appear that the periodicity is of a regular character. More frequent and continuous observations of the minima, however, are required to decide this question.

It appears from the curves representing these minor inequalities that the length of the principal of them is about 15,000 periods, this period from the most recent computations being

$$2\text{d. } 20\text{h. } 48\text{m. } 55{\cdot}60\text{s.} +$$
$$3{\cdot}694\text{s. } \sin(133^\circ - 0^\circ{\cdot}024\text{ E.}) + 1{\cdot}784\text{s. } \sin(16^\circ - \tfrac{1}{18}{}^\circ\text{ E.})$$

Tables are then given showing the influence of including these new terms in the comparison of observed with computed epochs of minima (*Astronomical Journal*, vol. xxii. pp. 39–42, 1901.

THE MELBOURNE OBSERVATORY.—The annual report of Mr. P. Baracchi, the Government astronomer at Victoria, has recently been issued. All the usual routine work in astronomy, meteorology, terrestrial magnetism, &c., has been carried on as usual, and considerable progress has been made in the endeavour to lessen the accumulated arrears of unreduced records.

With the astrographic instrument 261 plates have been obtained, including 63 chart triple exposures, 49 chart single exposures, and 39 catalogue plates. The chart series of single exposures of 60 m. is now complete. The new Repsold micrometer made from the designs of Sir David Gill is found to work very satisfactorily, and measurements are made at twice the former speed, dealing with about 170 stars per hour.

The Milne seismograph is now adjusted in position and a continuous photographic record of seismic disturbances will be started as soon as possible.

ROYAL ALFRED OBSERVATORY, MAURITIUS.—The annual report of Mr. T. F. Claxton, director of the Royal Alfred Observatory, has recently been distributed, giving details of progress made during the year 1900. The meteorological and magnetic observations have all been continued as in previous years, but much of the astronomical work with the prime vertical and equatorial had to be abandoned on account of the unhealthiness of the district. Photographs of the sun with the photoheliograph were taken whenever weather permitted, and 311 negatives with 301 prints were forwarded to the Solar Physics Committee.

THE SIGNIFICANCE OF CERTAIN FEATURES AND TYPES OF THE EXTERNAL EAR.

IN these days the search for some characteristic of the human body which will give unequivocal evidence of the mental nature of the individual still goes on as merrily as ever. To some men the bumps of the head tell everything; to others the lines of the palm are hieroglyphic expressions of the qualities of the brain, not to speak of what they tell of things past and events to come; in fact, there is scarcely a feature of the human body that has not, at one time or another, been advocated as an index of certain faculties, and now it is the turn of the external ear. Although not one of these many pretensions has ever stood the test of scientific investigation, or even that of a casual every-day experience, yet their advocates continue to thrive and abound unabated. If those handmaidens of the brain—the muscles of expression—those that set the eye and strengthen the mouth, fail to yield a clue, then it is vain to seek for it in any other structure of the body.

There are three classes of observers, however, which have made a special study of the external ear, deserving of the utmost consideration. The first of these is the school of workers founded by Lombrosa, which believes that *a certain class* of criminals are criminals because of an imperfection in the development of their brains. It is probable, as this school supposes, that such imperfectly developed brains will be wrapped in defective bodies; by the presence of bodily defects, and they have used very largely those of the external ear as an index, the imperfections and unbalanced nature of the brain may be detected. It is clearly a matter of the utmost moment for a State to be able to recognise its criminals, who are criminals because of their constitutional imperfections, and this undoubtedly is the aim of the Lombrosa school. In their investigations of the external ear they found certain features to exist in those of the criminal and insane classes with a much greater frequency than in the sane. With their results I wish to compare a wide series of observations made on the criminal and insane classes of this country.

FIG. 1.—Illustrating certain types of ear ret rred to in the text.

The second class of observers, which deserves attention, is that which has contributed to our knowledge of the development, anatomy and evolution of the human external ear. Its contributions make up quite an extensive literature. Prof.

Schwalbe, who may be regarded as the chief of this class, gives references to 145 papers[1] in his latest work on the ear—most of which deal only with the external ear.

The third class is that of which Bertillon[2] is the chief. To this class the characters of the external ear are important only so far as they may assist in the identification of the criminal. Its system of observation is purely empirical, and the large masses of facts which it has accumulated are useless for the scientific advancement of the subject.

In a paper contributed recently to *La Nature*,[3] from which Figs. 1 and 2 are borrowed, Mr. Henri Coupin remarks that way, for I suspect that most people, as well as the novelist, find a lack of descriptive terms by which the numerous varieties of the external ear may be fully indicated.

There are two types of ear which everyone must have noticed, although they have found no name for them. They are contrasted types and mark the opposite poles of ear development. One of these is that which the novelist occasionally condescends to notice, describing it as "a beautifully modelled, small, shell-like ear." Popularly it is regarded as a sign of high breeding. Examples of this type may be seen in Fig. 1, Nos 1, 5, 8, 11, 18, 20, 25, 27, and in Fig. 2, Nos. 8, 12, 16, 19, 25, 34, 35.

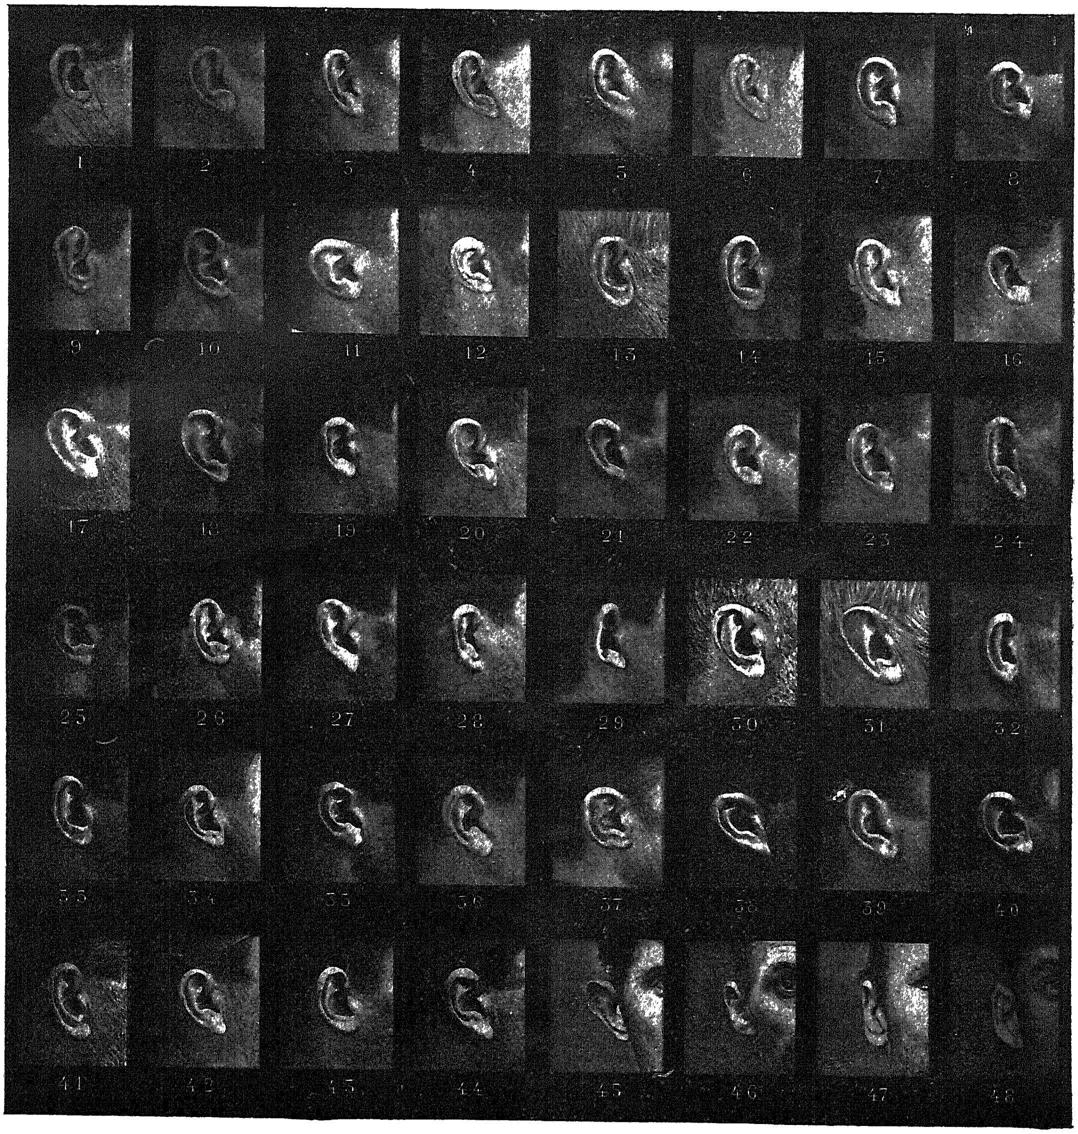


FIG. 2.—Illustrating certain types of ear referred to in the text.

writers of fiction, while describing with a fulness of detail the features of the eye, mouth, nose and hair of the heroine or hero, carefully abstain from any mention of the external ear. Yet there is no doubt that the ear is a subject of common remark among friends and acquaintances, but often in an inarticulate

An example of the same type will be seen in Fig. 3, which is a tracing from a photograph of a typical ear of the orang. For the reason that the chief features of the orang's ear are present in the type of ear I have just cited, I have named it the "orang-type" of human ear.

The type of human ear contrasted to this is one never alluded to in fiction, but is frequently the subject of everyday remark. It is large, expansive, and projects like "wind-sails from the port-holes of a steamer in the tropics." A very good illustration of it is seen in Fig. 2, No. 45, but further examples may

[1] "Handbuchs der Anatomie des Menschen," von Bardeleben. Abtheil ii. Band v., 1898.

[2] "The Bertillon System of Identification." Translated by McClaughry. 1896.

[3] "Notre Oreille," *La Nature*, p. 138, July 27, 1901.

be detected in the same figure, Nos. 13, 17, 31, and in Fig. 1, Nos. 9, 13, 15, 28, 29, 30, 35, 36, 38, 46. An ear of the same type is shown in Fig. 4; it is a tracing from the ear of "Sally," the chimpanzee, and is typical of her species. This may be called the "chimpanzee type" of human ear.

This nomenclature, of course, does not imply that people with the orang-type of ear are related any more to the orang than the chimpanzee-type indicates an affinity to the chimpanzee. The resemblances are due to the fact that in the orang the external ear has undergone marked retrograde changes; in the chimpanzee the ear has retained its pristine development. The one marks

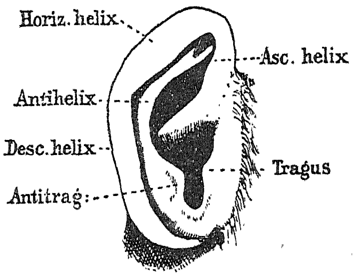

FIG. 3.—An Orang's Ear.

the ebb tide of retrogression, the other the full tide of development; the corresponding types in man mark the same extremes. The anatomical parts of the ears of the three great anthropoids and man are the same (see Figs. 3, 4, 5 and 6), but in men are found types exemplifying the retrograde changes which have overtaken the ears of all orangs, and also examples of the full development which marks the ears of chimpanzees. Curiously enough the gorilla, like man, shows an amplitude in the variations of its ear, but on the whole it inclines towards the orang-type.

But what is meant by retrogression, and what by full development of the ear? The explanation entails a reference to the seven parts which compose the outer ear. Each of the seven springs as a separate part round the opening of the ear in the embryo, and by the fourth month they have fused to form the whole structure.

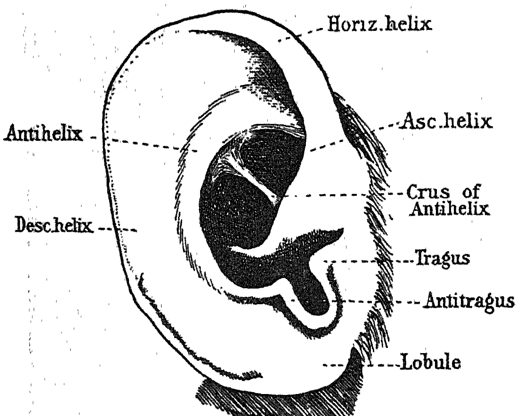

FIG. 4.—Ear of Chimpanzee.

Three of these parts surround the concha, or cavity, and opening of the ear-passage, viz. the tragus, the antitragus and the antihelix (see Fig. 5). The remaining four parts form the circumference of the ear, viz. the ascending helix—in front and above; the horizontal helix—above; behind, forming the wide posterior border of the ear—the descending helix; and below—the lobule. Now only one of these seven parts suffers *markedly* from progressive or retrogressive changes, and that is the descending helix. In Fig. 5 a human ear is represented—somewhat diagrammatically with the descending helix fully developed; that is to say the descending helix is wide, expansive, and its margin is not inrolled; the ear of the chimpanzee (Fig. 4) shows similar characters in its descending helix. On the other hand, the orang's ear (Fig. 3) shows the descending helix not only markedly reduced, but its margin, like that of a cankered leaf, is inrolled. A reference to the orang types in Fig. 1 (such as No. 11) and Fig. 2 will show inrolling of the margin of the descending helix, similar to that in the orang. The various degrees to which the inrolling may be carried is shown diagrammatically in Fig. 5. Four degrees of inrolling are recognised, viz. 0, 1st, 2nd or 3rd degree. It should be remarked, however, that the reduction in size of the descending helix and inrolling of its margin do not constitute all the characters of the orang type—with these the development of the ear as a whole also shows reduction in size. The height of the ear of a chimpanzee is nearly twice that of an orang, yet the orang is the larger animal of the two.

There is one prevalent conception of the human ear which I believe to be a mistaken one, and which I wish to correct now. It is usual to speak of it as a decaying structure. This is remarkable, if true, for with the introduction of speech the means of catching sound are more needed than ever. Although the helix, especially the descending helix, which in mammals generally makes up the greater part of their trumpet-shaped ears, has undergone and is undergoing retrogression in man, that part of the ear which bounds and deepens the concha, the antihelix (Fig. 5), has reached a development in man which it never had before. At least, no other primate shows such a development. That is the change which appears to be going on in man now,

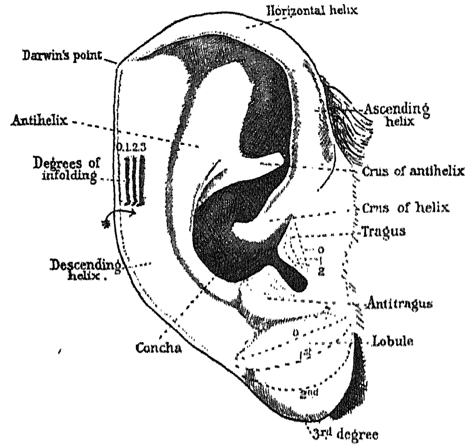

FIG. 5.—Diagram of the human ear.

viz., that in him a new type of ear is being evolved in which the antihelix plays the chief part in collecting sound-waves, while the circumference—the outer helix—undergoes retrogression. In this the orang-type of the human ear differs from the ear of the orang; in the orang the antihelix is in as retrograde a condition as the other parts of the outer ear, even the crus of its antihelix is only occasionally developed (Fig. 3); in the orang-type of the human ear the antihelix is especially well developed.

I should like to proceed at once and inquire into the relationship which those two types of human ears bear to the mental bias of the individuals in which they are found. But in order to avoid the mistakes made by the followers of Lombrosa on the Continent, it is necessary to allude to certain factors which have a powerful influence in determining the type of the external ear. I need not allude to age; that influences shape to some extent, but its effect is principally on its size. Schwalbe found that, on an average, the length of the ear increases 20 mm. from the twentieth to the eightieth year and the breadth at a corresponding rate. The ears of old people are always large and hence in my statistics I excluded those over sixty. This increase is a factor which those who use the ear for identification purposes should remember more than they do.

Sex is a powerful factor. The following table (table 1), in which are given the number of ears observed, the locality in which they were observed, the sex of the individual and the percentage in which the orang- and chimpanzee-types of ear occurred, will show its influence.

TABLE I.

Place.	No. of observations. Male.	Female.	Orang-type. Male. Per cent.	Female.	Chimpanzee-type. Male. Per cent.	Female.
Aberdeenshire	1135	776	27	40	14	5
London, E.	700	492	17	44	13	2
Jews (London)	109	62	16	51	17	8
Kerry	281	205	18	41	34	1
Carmarthen	296	256	18	48	19	6
Peterborough	306	227	19	50	19	6
Cork	256	245	24	50	28	3
Dublin	278	268	22	38	33	7

The table shows that the orang-type occurs in from 38 to 51 per cent. of women, while in men it varies between 16 and 27 per cent. Taking the average of this table, the orang-type may be said to occur in 18 per cent. of men and 45 per cent. of women. The chimpanzee-type, on the other hand, occurs four or five times more frequently in men than in women. That the orang-type should be characteristic of women and the chimpanzee of men is what one may expect; for in bodily characters, always excepting those of a sexual nature, woman apparently foreshadows the coming characters of the race.

My statistics are not sufficiently wide to allow of more than a partial statement as to the orang-type of ear being a sign of aristocratic birth, but of eight peeresses I find five have ears of this type, which certainly lends some support to the popular supposition. On the other hand, of five leading lady singers only one shows this type of ear.

Race, too, has an influence on the proportion with which the two types occur. That may be seen from Table I. The prevalence of the chimpanzee-type in Kerry, and the orang-type amongst the Jewish women may be noted. The orang-type occurs in about 90 per cent. of Hottentots; it is very frequent, although of a characteristic type, in certain races of negroes.

The ear-types, too, are correlated with the colour of the hair. In Table II. statistics are given of observations made at twenty-seven different localities of the United Kingdom.

TABLE II.

	No. of Observations. Male.	Female.	Orang-type. Male. Per cent.	Female. Per cent.	Chimpanzee-type. Male. Per cent.	Female. Per cent.
Fair-haired	2015	1127	31·3	46·7	15·8	4·1
Black-haired	1796	1463	15·8	40·3	36	4·7

The individuals with hair of intermediate shades of brown are omitted, and only those with distinctly fair or distinctly black hair are included. It will be seen that the orang-type occurs in fair-haired men twice as frequently as in black-haired men; the chimpanzee-type occurs in exactly the reverse proportion. Curiously enough the colour of hair scarcely affects the ear of the woman; black and fair show both types with an equal frequency. Both this table and the last draw attention to the fact that the variations in one sex are not necessarily correlated with those of the other.

It will be readily seen how necessary it is to consider those various factors which influence the ear before proceeding to consider the ears of those who have their liberty temporarily or permanently suspended because they are no longer able to conform to recognised social standards of conduct. The variation according to race or locality is wide (*vide* Table I.); sex and other qualities are influencing factors. In the following table (Table III.) are given the proportions with which the orang- and chimpanzee-types of ear occur (1) in habitual criminals, obtained through the courtesy of Dr. Garson; (2) the insane of four asylums in different parts of the kingdom; (3) congenital idiots.

TABLE III.

Locality.	No. of observations. Male.	Female.	Orang-type. Male. Per cent.	Female.	Chimpanzee-type. Male. Per cent.	Female.
Scotland Yard	326	208	35	33	15	12
Aberdeen Asylum	190	211	23	40	16	8
Durham Asylum	211	208	26	40	18	3
Cork Asylum	202	205	12	37	19	3
Dublin Asylum (Richmond)	189	204	29	33	12	3
Congenital idiots	27	9	26	66	4	0

Taking the insane first, it will be observed (compare Tables I. and III.) that on the whole the insane, so far as relates to the prevalence of the two types of ears, do not show a marked deviation from the sane of their neighbourhood and that there is no constant difference between the two classes. The insane men of Aberdeen and Cork show the orang-type less frequently than the sane; in Dublin the case is the reverse. In the insane women a similar variation is shown in the prevalence of this type; in one case it is lower, in another higher and in still another the same. It is so also as regards the chimpanzee-type. We must, therefore, conclude, so far as concerns these two types of ears, that there is no correlation between them and a bias towards insanity.

The congenital idiots show a prevalence of the orang-type, considerably above the average, and an occurrence of the chimpanzee-type below the average, but the number of the observations is too small to allow of any certain conclusion.

When, however, the confirmed criminal class is dealt with a striking departure from the normal is encountered—quite unlike the statistics gained from any other series of observations. The sexual ratio becomes inverted; the orang-type, instead of occurring in the female twice as frequently as in the male, which is the normal ratio in the sane, occurs with the greatest frequency in the male. So, too, with the chimpanzee-type, it is found almost as frequently in the female as in the male. In short, male criminals show a preponderance of the orang-type, female criminals of the chimpanzee-type. There is a reversion of the normal sexual ratio.

Thus it will be seen that, taken as a *class*, not as individuals, criminals show a departure from the sane in their physical constitution. But what does this really mean? It means, I take it, that the criminal class is recruited in undue proportion from the group of men who manifest the orang-type of ear and the women who possess the chimpanzee-type. A larger proportion of individuals of these two classes is predisposed towards crime than those with opposite types. But clearly the presence of the orang-type of ear in any individual is of itself no evidence of this predisposition.

I have already shown that the ratio in which these two types of ear occur is correlated with the colour of the hair. On comparing the colour of the hair of the criminal class with that of groups of people in various parts of the country, for the criminals I dealt with were drawn from almost every county, I found that the criminal class was drawn in an undue proportion from the black-haired men, in a lesser degree, also, from the black-haired women, and that therefore the orang-type should occur in them with a decreased, and not as it does with an increased, frequency.

Darwin's Point.—Since Darwin drew attention to the remnant of the tip of the human ear, an enormous literature has grown up around it. Vali found that it occurred with thrice the normal frequency in the insane; but before considering the relationship which its presence bears to an unstable mental equilibrium it is necessary to clear away some popular misconceptions that still prevail as to its nature.

It is not the case, as the following table (Table IV.) will show, that it is only in the human ear that the tip has become lost; it will be seen that this is also the case in all the anthropoids, a group that is genetically closely related to man. In all

Dublin	267	268	12	10
Cork	254	254	14	7

the anthropoids the tip occasionally recurs, showing that they come of a stock in which the ear was tipped. Only two groups of the old-world monkeys constantly retain the tipped form of ear—these are the macaques and baboons; in the other three groups of old-world monkeys (see Table IV.) the tip has already begun to disappear. It is probable, then, that the tipped form of ear began to disappear during an early stage in the evolution of the anthropoid and human stocks.

There can be little doubt that in the ear of the baboon or macaque (see Fig. 6) we have preserved for us approximately the form out of which the different types of ear seen in the higher Primates, including man, have been evolved. The tip occurs at the junction of the horizontal and descending helix; in this position it has to be looked for in man.

The complete or partial disappearance of the tip of the ear is part and parcel of the retrogression of the descending helix. When the descending helix (posterior border) becomes inrolled, then the tip is also inrolled. In the third month of fœtal life, the descending helix is not yet inrolled and the tip is constantly present on the human ear (Schæffer). Some trace or indication of the tip can be made out in 75 per cent. of adult men (Schwalbe). But in the statistics I give here relating to this structure, only those cases are included which showed Darwin's point in an unmistakable and pronounced form.

It is clearly evident from Table IV. that, before any deduction as to the presence of this structure on the ears of the criminal and insane classes can be made, the influence of race and sex must be taken into account. It is more frequently present in the male than the female; Schwalbe found it three times more so in the males of Upper Alsace, and this agrees with what I found in a typical English place, such as Peterborough.

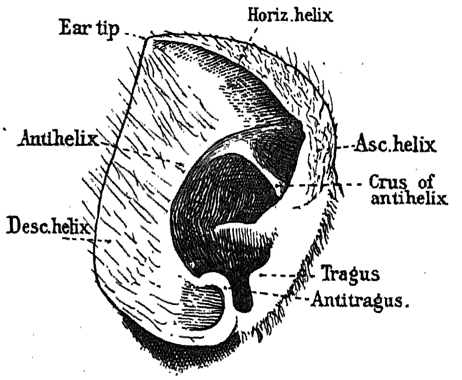

FIG. 6.—Ear of Macaque.

In the African negro it is rarely present; the helix of his ear has undergone so marked retrogressive changes; but in the Andamanese it is frequently present—more so in the women than men. The ratio of its presence varies widely with the race and locality.

In Table V. are given the results of observations made on (1) the insane, (2) criminals, (3) congenital idiots.

TABLE V.—*The Occurrence of Darwin's Tip in the Insane, in Criminals and in Congenital Idiots.*

Scotland Yard	328	201	27	17
Congenital Idiots	27	—	37	—

Unfortunately I have no "control" observations on the population from which the insane of Aberdeen and Durham are drawn, but in the case of Cork and Dublin I have, and it is seen that Darwin's point comes out in the insane with double the frequency, or rather more, than that with which it occurs in the sane. The criminals also show it with a much greater frequency than I have found in any locality throughout the country. Its frequency is especially marked in congenital idiots and those vagabonds that congregate at the doors of the police courts and night shelters in London and Liverpool.

[1] I am greatly indebted to the superintendents of these four asylums for the opportunities and help they afforded me.

Darwin's point, the structure which we now deal with, differs very materially in nature from the subject last considered, viz., the type of ear. The two types of ear were symptoms merely of progressive or retrogressive development, but Darwin's point is the persistence of an ancestral or, what amounts to nearly the same thing, a fœtal form, and with this persistence might be expected a correlated persistence, to some extent at least, of the ancestral faculties of the brain. This certainly does not hold true of the individual; it does to some extent of the mass. Clearly the insane and criminal classes are drawn with an undue proportion from those in which Darwin's point is pronouncedly present.

The Lobule.—Before concluding, I wish briefly to refer to this structure, because it differs in nature from the two features of the ear already considered. It is a structure of comparatively recent addition to the ear. It is not the case that it is a feature peculiar to man; it may be detected, as Table VI. shows, in the ears of the three great anthropoids, but it is only in man that it finds a full and almost constant development, and therefore may be regarded as a recently added and progressive structure.

TABLE VI.—*The Development of the Lobule in Anthropoids and Races of Men.*

Congenital idiots	27	9	1·2	1

It is necessary to allude to the manner in which the index of the development or size of the lobule was obtained. A reference to Fig. 5 will assist in the explanation. I became accustomed to measure with the eye the various degrees to which the lobule was developed and arranged them in four groups:—(1) those in which the lobule was extremely small or absent; (2) those in which it was developed to the first degree; (3) those in which it was developed to the second degree; and (4) those of the largest or third degree. Those degrees are indicated in Fig. 5. An index of 1·6, for instance, signifies that the average lobule in that group of individuals reached, in my artificial standard, 1·6 degrees of development. The method is not accurate; nothing less than actual measurements would render it so; but before such a laborious process is undertaken one requires to be assured that some very definite result will be accomplished. My method is accurate enough for the purposes of comparison and for eliciting any decided factor which may be at work.

It will be seen that it is the case with the lobule as with the two other features of the ear, that its development varies with sex and race. It is larger in the female than in the male; it is larger in the white races than in the black.

Its development in the insane and criminal classes does not depart to any marked extent from that of the normal classes. In the insane of Aberdeen and Dublin, the lobule was smaller than that of the sane of the same localities, but in Cork the difference was rather the reverse. It appears to reach an average development in criminals, but in congenital idiots, on the other hand, it rather approaches the degree of development met with in the gorilla.

To sum up. This investigation was originally undertaken to see how far the characters of the external ear might

be utilised in unravelling the genetic connection of human races; it was only incidentally, when I became aware of the extraordinary degree of individual variation, that I was drawn into the investigation of features which have been described as "marks of degeneration." The result of my inquiries in this direction has been to show that only two out of the seven features of the external ear which I investigated are correlated with a mental bias towards crime or insanity, viz. a retrograde development of the helix and a persistence of the ear tip.

My results are the more valuable because I was at first sceptical of the very definite results obtained by continental observers on the insane and criminal classes. It appeared very probable that the definiteness of their conclusions would disappear if allowances were made for the populations from which the criminals and insane were drawn and for the influence of race, sex and colour. After making those allowances, however, there remain a certain number of characters peculiar to these classes, of which those I have cited in the ear are only examples. But, unfortunately for any practical application of Lombrosa's doctrine to the detection of the socially unfit, the physical differences between the sane and the insane or criminal classes are those of degree or ratio, not of kind. The characters may assist in the detection of the class, but not of the individual.

All that can be deduced from the present investigation is that a slightly greater proportion of the people who have ear tips and retrograde helices give themselves over to crime than those in which these two features are absent. The evidence is just sufficient to justify the suspicion that a small proportion of criminals are criminals because of their physical constitution, and it is certainly the duty of every anatomist to discover how such individuals may be recognised. As yet all the criminal marks we know of can only be stated in relative terms of the class, and have, unfortunately, no application to the individual.

ARTHUR KEITH.

SCHOOL BOARD EXHIBITION OF SCIENTIFIC APPARATUS.

ONE of the reasons often given as an excuse for not introducing instruction in the elementary principles of science into the curriculum of elementary schools is the expense involved in providing the necessary apparatus for experimental demonstrations. It is common to find that school managers have very exaggerated ideas as to the amount of really necessary equipment. Though it has been the custom for some years, at institutions like the Royal College of Science, to instruct the students in training to become science teachers how effective apparatus can be made at a very small cost and with a minimum of mechanical dexterity, the great majority of science teachers, notably those of elementary schools, have had few opportunities of acquainting themselves with the use that may be made of the odds and ends of domestic life to construct instruments which can be effectively used in simple work in experimental science.

The School Board for London has recently taken steps to remedy this defect in the training of its teachers. Influenced by the heavy expenditure on apparatus to which it has been put, and convinced that the construction of simple instruments can be made a valuable assistance in teaching science, the Board has for some months encouraged its teachers to make apparatus themselves and to give their pupils opportunities of making models to illustrate the principles of the lessons they have received. The exhibition at the Examination Hall on the Embankment (see NATURE, p. 656) represents the results of these efforts up to the present time. Though satisfactory if considered as the first exhibition and as showing that an earnest attempt is being made to give science its proper place in training children for the business of life, there are some directions in which improvement is easily possible. It must be understood that in pointing these out we do not lose sight of the difficulties the organising committee has had to overcome, but desire simply to suggest what may be done to ensure a better set of exhibits next year.

In the present exhibition the work of teachers, adult students in evening classes and children in day schools are indiscriminately mixed up. The work of comparison is consequently very difficult, and it is to be feared that the boys and girls will be a little disheartened to find their work side by side with that of their instructors and their big brothers in the continuation school. Nor is it easy to form an idea of the work of the pupils of different schools. It is only after consulting a catalogue, or reading a label affixed to the exhibit, that the visitor is able to find the school from which the maker of the apparatus comes. It would be better in the future to have together typical sets of apparatus from different schools.

It is difficult to estimate the relative importance given to different branches of science by the Board. There is a large number of exhibits in statical electricity, but only two pieces of apparatus shown in connection with the study of light and three to illustrate the teaching of physiography. The subjects of heat and voltaic electricity are, judging from the number of exhibits, popular, while acoustics meets with very scant recognition. It is disappointing, too, to find so little attention given to Nature-knowledge. From the conditions of city life it is hard for children to get even a nodding acquaintance with the beauties of organic life, whether animal or vegetable, and the school should be able to help the youngsters to learn something of the joys of country life. So much has been accomplished in recent years in the direction of providing simple school museums of common botanical and zoological objects, that it is to be hoped the teachers and scholars will be encouraged to do something in this direction. Then, why is nothing done to familiarise the children with the "starry heavens"? We looked in vain for a simple home-made telescope. Yet teachers have been shown for many years past in the astrophysical laboratory at South Kensington how a really effective instrument can be made with cardboard tubes at a trifling expenditure.

But a good beginning has been made. If more attention is in the future given to some of the subjects we have indicated, and if the work of teachers is separated from that of the taught, the utility of the exhibition will be much enhanced.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—An election to the Isaac Newton Studentship in Physical Astronomy and Optics will be held next term. Candidates must be Bachelors of Arts under twenty-five on the first day of 1902. The studentship is of the value of 200*l*., tenable for three years. Applications are to be sent to the vice-chancellor between January 16 and 26.

On November 4, Mr. R. P. Paranjpye, the Indian student who was bracketed senior wrangler in 1899, was elected to a fellowship at St. John's College.

PROF. WILLIAM RAMSAY, F.R.S., commenced a course of twelve lectures on "The Recent Developments of Chemical Theory" at University College, London, on Friday last. This course is especially designed for those who have a previous acquaintance with inorganic and organic chemistry and who may wish to know the present standpoint of chemical thought.

AT the annual meeting of the governors of Dundee University College last week Mr. John Morley referred to the signs of increasing interest in universities and the increasing force which must be given to the movement in order to put ourselves in the position of other progressive nations. He hoped that the movement had not yet attained full flood, because "all those who inquired into the conditions of scientific training in Germany and the United States were really—he was not using an excessive word—dismayed when they found the comparative shabbiness and meagreness of the buildings, funds and equipments in this island. There was no form of care for the public weal more distinctly certain of being reproductive than that care which placed within the reach of the coming generation opportunities for making the best of itself and giving to the Commonwealth the best of its faculties. That was now a commonplace. The immediate question was, what was to be done in order to raise Dundee and other places in Scotland up to the level which public necessities—national necessities—Imperial necessities if they liked—demanded?" The answer is—and it will serve for practically all institutions for higher education in the British Isles—Increase the teaching resources by building and equipping laboratories, encourage original work rather than the multiplication of successes in examinations, create in the public mind a spirit of sympathy with scientific work, and inspire the Government to action before it is too late.

A SCHEME for the extension and better equipment of the University of Glasgow, especially in the departments of

medical and physical science, was approved at an influential meeting of members and friends of the University held in the Glasgow City Chambers last week. Addressing the meeting, Principal Story said that in the beginning of the present year an executive committee was formed to provide funds for carrying out the measures of extension and reform considered of primary importance, and already they had received a sum of more than 62,000*l.*, including 10,000*l.* given for a special lectureship. It was proposed to make good the defects by the erection of additional premises for the class rooms, departmental museums, and laboratories of physiology, materia medica and forensic medicine, and public health. The needs of the chemical department, which could be regarded as belonging both to the faculty of science and to that of medicine, might be met, but only partially and temporarily, by the transference of premises available when physiology was provided for. A set of thoroughly furnished chemical laboratories is one of the most immediate wants, and additional accommodation is needed by the department of physical science. The full realisation of these designs must necessarily be a work of time, and will cost in all probably not far short of 100,000*l.* But it is encouraging to know that within the last few months more than the half of this sum has been subscribed. For the other half the University must depend upon the generosity of its many friends.

SCIENTIFIC SERIALS.

American Journal of Science, October.—On galvanometers of high sensibility, by C. E. Mendenhall and C. W. Waidner. A description of the design and manufacture of a delicate galvanometer of the four-coil Thomson type. There is a detailed discussion of the methods for obtaining the highest sensibility and also of the causes of the changes of zero.—On a method of locating nodes and loops of sound in the open air, with applications, by Bergen Davis. A small mill-like arrangement, constructed by placing four hollow cylinders of gelatine at the end of cardboard arms in such a manner that the closed ends pointed in the same angular direction, was mounted in the mouth of a resonator with the plane of the system perpendicular to the mouth. The resonator was in unison with an organ pipe, and when the pipe was blown the mill was found to rotate with a high velocity, the position of the nodes and loops being readily determined with considerable accuracy. In the open air the effect could be observed up to about sixty feet from the pipe.—The anatomy of the fruit of *Cocos Nucifera*, by A. L. Winton.—Studies of Eocene mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman.—A new crinoid from the Hamilton of Charlestown, Indiana, by E. Wood.—On the estimation of cæsium and rubidium as the acid sulphates, and of potassium and sodium as the pyrosulphates, by P. E. Browning.—Time values of provincial carboniferous terranes, by C. E. Keyes.—The spectra of hydrogen and some of its compounds, by John Trowbridge. The vacuum tubes used in the experiments described were illuminated by a current derived from a large battery of storage cells and not from a Ruhmkorf coil. The conclusions drawn from these investigations, which are at variance with the views generally received, are that hydrogen is an insulator, the passage of electricity through hydrogen, oxygen, nitrogen and their gaseous compounds being conditioned by the water vapour present. Certain carbon bands are always present in glass tubes filled with hydrogen, nitrogen, oxygen and ammonia gas, notwithstanding the greatest care taken during filling. The X-rays excited by the application of a steady current are due to the radiations set up by the dissociation of highly rarefied water vapour.

Bulletin of the American Mathematical Society, October.—Prof. F. N. Cole gives an account of the proceedings at the eighth summer meeting of the Society, held at Cornell University, Ithaca, New York, August 19–24. It was a largely attended meeting, and various circumstances made an adequate provision of time for the reading and discussion of the thirty-two papers presented practically impossible. The titles and abstracts occupy more than twenty pages. The third colloquium of the same Society was also held on the same date. Dr. Kasner gives an abstract of the proceedings at the two previous colloquia, as well as of this one. During the four days, two courses of four lectures each were delivered by Prof. Oskar Bolza, on the simplest type of problems in the calculus of variations, and by Prof. E. W. Brown, on modern methods of treating dynamical problems, and in particular the problem of three bodies. Grateful acknowledgments were made of the hospitality of the University and for the numerous privileges which were afforded to the members present. Short notices are given of two of the papers: upon the non-isomorphism of two simple groups of order 8!/2, by Miss Schottenfels, and concerning surfaces whose first and second fundamental forms are the second and first fundamental forms respectively of another surface, by Prof. A. Pell. Extensive notes of the mathematical courses for the session 1901–1902 at several Universities follow, with other matters of personal interest. Several pages are also devoted to new publications.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, October 2.—The Rev. Canon W. W. Fowler, president, in the chair.—Mr. G. C. Champion exhibited a long series of *Buprestis sanguinea*, Fabr., from Albarracin, Spain, showing the remarkable dimorphism of this species.—Mr. H. St. J. Donisthorpe exhibited on behalf of the Rev. H. S. Gorham, of Shirley Warren, a specimen of the scarce beetle, *Hister marginatus*. He also exhibited a number of rare Coleoptera from the New Forest, including *Velleius dilatatus*, F., from hornets' nests, *Anthaxia nitidula*, L., *Agrilus sinuatus*, Ol.—not taken for many years—*Agrilis viridis*, L., *Platydema violaceum*, F., a species also not recorded recently, and *Collydium elongatum*, F., one specimen taken in the burrows of *Melasis buprestoides* and another in the burrows of *Scolytus intricatus*. Mr. Champion said that Mr. George Lewis associated *Velleius* with *Cossus* and not with hornets.—Mr. C. P. Pickett exhibited varieties and aberrations of *Lycaena corydon* taken during August at Dover, and a series of *Angerona prunaria* (bred June and July), the results of four years' interbreeding, showing a wide range of coloration.—Prof. T. Hudson Beare exhibited a specimen of *Medon castaneus*, Grav., taken at the edge of a pond in Richmond Park.—Mr. A. Harrison exhibited a series of *Amphidasys betularia* bred from parents taken in the New Forest in 1900, including six gynandromorphous specimens.—Mr. C. J. Gahan exhibited a male specimen of *Thamnotrizon cinereus*, L., one of the long-horned grasshoppers taken by Mr. F. W. Terry at Morden, near Wimbledon, and called attention to a very interesting abnormality displayed by the specimen in possessing two pairs of auditory organs instead of a single pair, the second pair being situated on the tibiæ of the middle legs in a position corresponding with that of the normal pair on the fore-legs.—Mr. F. Merrifield exhibited a series of *O. antiqua* much darker than the type, bred from pupæ placed in a refrigerator five weeks and then exposed to a mean temperature of 48° F.—Mr. R. South communicated a paper by the late Mr. J. H. Leech, entitled "Lepidoptera-heterocera from China, Japan and Corea (Pyralidæ)"; Mr. G. C. Champion contributed notes and observations upon the sexual dimorphism of *Buprestis sanguinea.*

October 16.—Mr. E. Saunders, vice-president, in the chair.—Mr. C. Morley exhibited for the Rev. E. N. Bloomfield leaves of hornbeam from Battle, and a photograph of leaves of sweet chestnut from Haslemere, rolled by *Atelabus circulionoides.*—Mr. R. Adkin exhibited a specimen of *Pieris daplidice* taken by him at Eastbourne on August 19 last. He said that the insect was flying strongly, and in that respect and indeed in general appearance resembled on the wing a pale female of *Colias hyale.*—Mr. C. P. Pickett exhibited series of *Melitaea cinxia* bred in June last from larvæ taken in the Isle of Wight, including light and dark varieties, and a series of *Choerocampa elpenor* bred in June last from larvæ taken at Broxbourne in July 1900, including a variety of the male with purplish lower wings and another with purple markings on the upper wings.—The Rev. F. D. Morice exhibited specimens of *Hedychrum rutilans*, Dhl., and *Salius propinquus*, Lep., taken at Lyndhurst by Miss Ethel Chawner, and both new to the British list. He also exhibited two monstrosities, viz. *Allantus arcuatus*; (sawfly) with two perfect wings, and two other imperfectly developed wings on the left side, and *Gorytes quinquecinctus* (fossor) with the abdominal segments extraordinarily twisted out of their proper shape and places.—Mr. Arthur M. Lea communicated a list of the Australian and Tasmanian Mordellidæ, with descriptions of new species; and Mr.

Edward Meyrick, descriptions of new Lepidoptera from New Zealand.—Mr. E. Saunders then read a paper upon Hymenoptera aculeata collected in Algeria by the Rev. E. A. Eaton and the Rev. F. D. Morice, part i., Heterogynæ and Fossores to the end of Pompilidæ.

Royal Microscopical Society, October 16.—Mr. Wm. Carruthers, F.R.S., president, in the chair.—Messrs. C. Baker exhibited a portable microscope on the model of the "Diagnostic," originally designed for Major Ronald Ross's investigations of malaria. It is made of magnalium, an alloy of manganese and aluminium, and weighs but fourteen ounces. This firm also exhibited a microscope intended for the examination of fractures and etched surfaces of metals. The instrument is provided with vertical illuminator, and rack and pinion focussing adjustment and levelling screws to the mechanical stage, now usual in this class of instrument.—Messrs. R. and J. Beck exhibited a portable model of their "London" microscope, which, by the introduction of several ingenious devices, could be packed with the apparatus into a leather case $2\frac{1}{4}$ inches × $4\frac{1}{2}$ inches × $9\frac{1}{2}$ inches. Messrs. Beck also exhibited a centrifuge, made to run at a high speed by an electric current.—The president showed some specimens of the mycetozoa and gave a brief account of the life-history of this group of organisms. The specimens belonged to a recently described species and had been named *Badhamia foliicola*. He directed attention to the exhibits by Mr. C. L. Curties consisting of a number of mounted specimens of marine zoological objects, accompanied by very full and interesting descriptions.—The president gave a *résumé* of a paper, by Miss A. Lorrain Smith, on fungi found on germinating farm seeds. Miss Smith had been assisting him in his work for the Royal Agricultural Society in examining farm seeds in respect to their germinating power. In the course of their observations Miss Smith had found numerous species of fungi on the germinating seeds, fourteen species in all, of which five were new and one belonged to a new genus.—The secretary announced the receipt of part xiv. of Mr. Millett's report on the foraminifera of the Malay Archipelago, which was taken as read.

Manchester.

Literary and Philosophical Society, October 15.—Mr. Charles Bailey, president, in the chair.—Mr. R. L. Taylor remarked that he had noticed that the Manchester water appeared to contain an unusual amount of dissolved chlorides at the present time, and, on roughly estimating the amount of dissolved solids, found that the total had, curiously enough, gone up from a normal amount of about $4\frac{1}{2}$ grains to about $9\frac{1}{2}$ grains per gallon, due, no doubt, to the recent scarcity of water and to the concentration by evaporation on the gathering grounds and in the reservoirs.—Mr. R. D. Darbishire exhibited a large collection of the Eolithic implements of the Kentish plateau, and illustrated with map and section the outline of the denudation of the valley of the Weald, leaving a drift deposit on the remaining chalk of the north and south encarpments. In the process many levels of river gravels had been fixed, and partly occupied by stone implements of successive ages, mostly much mixed up in the redisposition of the gravels by succeeding movements. He described the general facies of the so-called Palæolithic implements from river deposits in France and England and their peculiar modes of manufacture by "chipping" or flaking, and shapes; and confessed inability to determine the uses of such tools or any characteristics of the men who made them. They were fossil indications of man with mind, skill, and purpose, and that was all.

October 29.—Mr. Charles Bailey, president, in the chair.—Dr. C. H. Lees was elected to the office of honorary secretary in succession to Prof. A. W. Flux.—Mr. C. E. Stromeyer read a paper on explosions of steam-pipes due to water-hammers, dealing with the subject both from a theoretical and practical point of view. He referred to the reports of the Commissioners of the Board of Trade, according to which about fifty steam-pipe explosions have occurred from the above causes during the last seventeen years, and said that the majority were brought about by the opening of drain-cocks of steam-pipes in which water had accumulated, while a few were clearly due to a plug of water having been shot from the boiler ends of the pipes to the engine-ends. Mr. Stromeyer first investigated the pressure which is set up when an elastic body suddenly comes to rest, the solution of which problem was correctly guessed at by Dr. A. Ritter in 1889, but he was unable to give a proof of the possibility of discontinuity of motion, which is part of the phenomena of an elastic blow. This point was illustrated by means of an unloaded helical spring. Having established this theory, it follows that when an elastic prismatic body is moving axially its front surface comes to rest instantaneously on contact with an unmovable obstacle, while the more distant parts of the bar come to rest also instantaneously when the wave of pressure or of change of velocity reaches them. This wave travels with the velocity of sound, and as the tail end of the bar has maintained its velocity, the axial pressure in the bar is the product of the elasticity of the material into the ratio of the velocity of the object to the velocity of sound. With the help of this theory it is easy to calculate the pressure which a plug of water of a given length travelling a given distance under the influence of a given pressure will exert if brought to a full stop.—A paper entitled "A Preliminary Note on the Preparation of Barium" was read by Mr. Edgar Stansfield. Results were given of a critical study of hitherto proposed methods of preparing metallic barium. The most promising results were obtained by the Goldschmidt process, by which alloys of barium and aluminium containing up to 60 per cent. of barium were produced, when the experiment was carried out *in vacuo* to avoid the formation of oxides and nitrides.

Paris.

Academy of Sciences, October 28.—M. Bouquet de la Grye in the chair.—Experiments on some chemical reactions determined by radium, by M. Berthelot. A comparison of the action of light and of the radium rays in promoting certain chemical reactions. The reactions used were the decomposition of iodic acid, of anhydrous nitric acid, the oxidation of oxalic acid, and the polymerisation of acetylene. In the first two cases the action of the radium rays was exactly similar to that of light, except that the action was much feebler; in the two latter experiments no action was observed. It is suggested as possible that the glass vessels, in which the radium salts were necessarily enclosed, may have cut off that portion of the rays which is capable of the most energetic effects.—On the heat disengaged in the reaction between free oxygen and potassium pyrogallate, by M. Berthelot.—On a prehistoric lamp found in the cave of La Mouthe, by M. Berthelot. An examination of the carbonaceous substance scraped off a prehistoric lamp found by M. Em. Rivière showed that these residues are similar to those which would be left after combustion of a fatty material of animal origin, badly separated from its membranous envelopes.—The junction of a closed network of trigonometrical triangles, by M. P. Hatt. An application of the method of least squares to the method previously developed.—On the flagella of the undulating membrane of fishes (*Trypanosoma*), by MM. A. Laveran and F. Mesnil. The existence of organisms with undulating membrane and with two flagella would appear to be doubtful, and the authors regard the creation of a new genus for these organisms as necessary, and propose the name *Trypanoplasma*.—On Foucault's top, by M. A. S. Chessin.—On the stability of commutators, by M. Maurice Leblanc. A discussion of the cause of irregularity in the motion of a commutator in connection with a number of accumulators, and of the methods of overcoming this.—The minimum value of the total heat of combination, by M. de Forcrand. By an expansion of a formula given in a previous paper the minimum value of the total heat of combination can be calculated. This has been done for a considerable number of substances, and these compared with experimental data as far as available.—A contribution to the study of the copper-aluminium alloys, by M. Leon Guillet. The alloys were obtained by heating aluminium with pure oxide of copper. By the application of this method, which had previously given successful results with molybdic and tungstic acids, three compounds could be isolated, Cu_3Al, $CuAl$ and Al_2Cu. These had been already prepared by a different method by M. Chatelier.—On the separation of iron, by M. Paul Nicolardot. Ferric chloride, after being heated to 125° C. for some hours, forms an insoluble sulphate on adding ammonium sulphate to its aqueous solution. No other metals likely to be present in iron or steel are precipitated. The analysis of certain special alloys is rendered very simple by this method.—The qualitative and quantitative determination of traces of antimony in the presence of large proportions of arsenic, by M. G. Denigès. Two methods are suggested, the first depending upon the separation of the antimony by metallic

tin in a platinum dish, and the second upon the formation of a double salt with cæsium iodide, and examination under the microscope of the crystalline deposit.—Researches in plants on cane sugar with the aid of invertin and of glucosides with the aid of emulsin, by M. Ed. Bourquelot.—On the estimation of the alkalinity of the blood, by MM. August Lumière, Louis Lumière and Henri Barbier. After a comparison of the results obtained by various methods that have been suggested the authors adopt an iodometric method, the results given in this way being regarded as much more exact than those obtained in the usual way.—The liberoligneous bundles of ferns. The union and separation of the liberoligneous elements, and some consequences, by MM. C. Eg. Bertrand and F. Cornaille.—On two states of the living substance, by M. Felix Le Dantec.—Remarks concerning the formation and origin of fine pearls, by M. L. G. Seurat. A criticism of the theory put forward by M. R. Dubois.—The nematod of the beet-root (*Heterodera Schactii*), by M. Willot.—On the mode of production of divergent luminous rays at 180° from the sun, by M. G. Sagnac.

NEW SOUTH WALES.

Royal Society, September 4.—Mr. H. C. Russell, F.R.S., president, in the chair.—Recurrence of rain—the relation between the moon's motion in declination and the quantity of rain in New South Wales, by H. C. Russell, F.R.S. The paper was essentially a continuation of that on the periodicity of good and bad seasons, read June 3, 1896. The author stated that while coastal rains were irregular, those of the interior showed a 19-year periodicity. Regretting that observations did not extend over a more lengthy period, it was pointed out that some rain records of Horsham, Victoria, dating back to 1848 were valuable, our first record at Bathurst beginning in 1858. To minimise possible errors, the averages of neighbouring stations were taken. An illustrative diagram accompanied the paper, the author stating that between 1850 and 1851, 1869 and 1870, and 1888 and 1889, the thick vertical lines—nineteen years apart—divided the records in "natural spaces" in which the first six years had abundance of rain, and the remainder was a "dry period." The first bad year of the series we were stated to be now in was 1895, the loss of sheep from starvation between 1895 and 1900 being alleged to be 25,000,000, not including the loss of 20,000,000 natural increase. The diagram showed also the curve of extreme southerly declination of the moon for each year. The author, in conclusion, stated that rain is shown for three periods of nearly nineteen years each, "to come in times of abundance when the moon is in certain degrees of her motion south, and when the moon begins to go north, the droughty conditions prevail for seven or eight years," which he says is "either a marvellous coincidence, or it is a law connecting the two phenomena," and he is convinced that there is some connection between the two.—The theory of city design, by G. H. Knibbs. The subject was systematically treated under the following headings: (1) introductory; (2) general idea of a city; (3) radial street-system; (4) position of radial centres; (5) combination of radial and rectangular street-systems; (6) curved streets; (7) cardinal direction of rectangular streets; (8) width of streets; (9) localisation of the various types of street; (10) grade and cross-section of streets; (11) engineering features of streets; (12) size of blocks between streets; (13) height of buildings; (14) theory of aspect; (15) the æsthetics of design; (16) sites for monumental buildings and monuments; (17) treatment of street; from the standpoint of æsthetics; (18) public parks and gardens; (19) hygienic elements of design; (20) the preliminaries of design; (21) conclusion.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 7.

LINNEAN SOCIETY, at 8.—On the Life-history of the Black-currant Mite (*Phytoptus ribis*): Mr. Warburton and Miss Embleton.—Notes on the types of Species of *Carex* in Boott's Herbarium: C. B. Clarke, F.R.S.

RÖNTGEN SOCIETY, at 8.30.—Presidential Address: Herbert Jackson.

A CANADIAN NATURALIST.

Wild Animals I have Known. By Ernest Seton-Thompson. (New York City: Scribner and Sons.)

The Trail of the Sandhill Stag. (New York City: Scribner and Sons.)

The Biography of a Grizzly. (New York: *The Century* Company.)

MR. ERNEST SETON-THOMPSON, Naturalist to the Government of Manitoba, is an American author and artist whose works enjoy a wide popularity in his own country, but are less known than they deserve to be on this side of the Atlantic. He has written books on the birds and mammals of his State and done other more or less scientific work, but owes his fame, perhaps, rather to three lighter volumes, beautifully got up and illustrated by himself, with the assistance of his wife, the companion in his later wanderings. These are "Wild Animals I have Known," first published in 1898 and already, early last year, in an eighth edition; "The Trail of the Sandhill Stag," and latest, and perhaps most powerful of the three, "The Biography of a Grizzly."

The full-page drawings in all three books are finished works of art, and many of the little marginal sketches—scraps of boughs and berries, and suggestions in a few strokes of footprints in the snow and woodland and mountain scenes—would have delighted Ruskin.

At one time in his life a wolf-trapper, Mr. Seton-Thompson is, in the highest sense of the word, a field naturalist; and, gifted with a poet's imagination, has identified himself, with a completeness which few writers have reached, with the wild creatures whose lives and surroundings he paints. The key-note of his writings is struck in the preface to the first of the three books:—

"A moral as old as Scripture, We and the beasts are kin. Man has nothing that the animals have not at least a vestige of, the animals have nothing that man does not in some degree share. . . . They surely have their rights."

When caught hand and foot in wolf traps which he had been carelessly setting, and from which in the end he was freed only by the intelligence of a faithful dog, who, after one or two fruitless attempts to help him, brought him the trap wrench which had lain just beyond his reach, he remembered as the prairie wolves howled round him, drawing closer and closer, "how old Giron, the trapper, had been lost, and in the following spring his comrades found his skeleton held by the leg in a bear trap," and a "new thought came to him"—"This is how a wolf feels when he is trapped." "Yan," in "The Sandhill Stag," alone and far from help of any kind, on the trail of the muckle hart, in the mid-winter moonlight hears across the frozen snow the gathering hunting cry of the wolves, nearer and nearer, until it suddenly flashes upon him, "It is my trail you are on! You are hunting me." When at last within fifteen feet of "the great ears and mournful eyes" of his tired-out quarry, he remembers how he felt then, and cannot shoot. He had "found the Grail," and "learned what Buddha learned" more than 2000 years ago.

Where all alike are excellent, none can well be best; and of the wild animals which Mr. Thompson "has known" and writes of it is not easy to make a choice.

There is the "Springfield fox," who shook the dogs off when she thought proper by "the simple device of springing on a sheep's back," and who, when, in spite of gunshots, she had tried for three nights to bite through the chain which held her cub, and found all her attempts to free him useless and danger faced for nothing, brought him poison and was never again herself seen or heard of in the neighbourhood.

There are "Wully," the four-legged Jekyll-Hyde, a faithful sheep-dog by day; and at night a treacherous, bloodthirsty monster, who, when found out, flew straight at the throat of the girl to whom he had always professed especial devotion; and "Silverspot," the canny old leader of the band of crows which had their head-quarters on a pine-clad hill near Toronto; and others, not less interesting, sketched by a master-hand.

The most striking figure in the first book, second only, if second, to the grizzly who has the honour of a volume to himself, is "The King of Currumpaw," a great wolf who, with his pure white mate and a chosen band of five, all wolves of renown, terrorised one of the vast cattle ranges of New Mexico, and with a price of 1000 dollars on his head—an unparalleled wolf-bounty—scorned all hunters, "derided all poisons, and continued for at least five years to exact tribute from Currumpaw ranches to the extent, many said, of a cow each day."

The band seldom condescended to eat mutton, confining themselves almost entirely to the best cuts of year-old heifers; but for the mere fun of the thing stampeded and killed sheep by hundreds.

Mr. Thompson gives an instance of the grim bandit's diabolic cunning which came under his own observation.

"Sheep," he writes, "are such senseless creatures that they are liable to be stampeded by the veriest trifle, but they have deeply ingrained in their nature one, and perhaps only one, strong weakness, namely, to follow their leader. And this the shepherds turn to good account by putting half a dozen goats in the flock of sheep. The latter recognise the superior intelligence of their bearded cousins, and when a night alarm occurs they crowd around them, and usually are thus saved from a stampede and are easily protected. But it is not always so. One night in last November two Perico shepherds were aroused by an onset of wolves.

"Their flocks huddled around the goats, which, being neither fools nor cowards, stood their ground and were bravely defiant; but, alas for them, no common wolf was heading this attack. Old Lobo, the weir-wolf, knew as well as the shepherds that the goats were the moral force of the flocks, so hastily running over the backs of the densely packed sheep, he fell on these leaders, slew them all in a few minutes, and soon had the luckless sheep stampeding in a thousand different directions."

It was not until "the grand old outlaw" had lost his consort and become reckless, following her body to the ranch-house and tearing the watch-dog to pieces within fifty yards of the door, that he met his end at the hands of his biographer, who had come by special invitation to the Palette Ranch to match his cunning with the great wolf's.

"Wahb," the hero of the book last on the list, is, like the king wolf (whose portrait, admirably drawn—"Lobo,

Rex Corrumpæ"—appears at the end of his memoir), a real character—a sullen and solitary bear of enormous size, responsible for the deaths of at least two cowboys, and believed never to have had a mate. He was known far and wide over a broad district of New Mexico as "the worst grizzly that ever rolled a log in the Big Horn Basin"; but in the Yellowstone, where for some years he regularly passed two months in summer, and where, as in our London parks—to compare small things with great—wild things at once grow tame, he managed to pass himself off as "a peaceable sort."

From facts gathered from hunters, miners and ranchmen, and from personal experiences, Mr. Thompson has imagined and written his life through "cubhood," "days of strength" and "waning," from the time when he and his two brothers and a sister—an unusually large family for a grizzly—as woolly cubs "hustled and tumbled one another in their haste to be first at the ant-heaps which a mother's strong arm unroofed, and squealed like little pigs, and growled little growls, as if each was a pig, a pup and a kitten all rolled into one," until the time when, a grey-bearded old bear, crippled with rheumatism, dethroned and driven from his haunts by a usurper whom a year or two before he would have despised, he limps "with shaky limbs and short uncertain steps to the mysterious 'Death Gulch'—that fearful little valley where everything was dead and where the very air was deadly," and "as gently went to sleep as he did in his mother's arms by the Gray-Bulls long ago."

It is a powerfully written and wonderfully graphic story, more particularly in the earlier chapters, where the poor little cub, sole survivor of the family, wanders motherless in the woods, with all the world against him, to learn by the slow lessons of experience all about traps and guns and beasts and, worst of all, men, and the meanings of the many subtle messages which reached the brain by way of his "great moist nose," storing up wrath against the day of vengeance, which came with his strength.

One of the most interesting things in the book is the account of the way in which a big bear, when he takes possession of a country, advertises his proprietary rights by rubbing himself, whenever he passes, against particular trees.

"Wherever Wahb went he put up his sign-board—
'TRESPASSERS BEWARE!'
It was written on the trees as high up as he could reach, and everyone that came by understood that the scent of it and the hair in it were those of the great grizzly Wahb."

A critic, to assert his superiority, must pick holes somewhere. Perhaps in the case of Mr. Seton-Thompson's almost altogether perfect work, the least unreasonable way of doing what is expected is by hinting a doubt whether the vein of melancholy which runs through much of his writings is not a little strained.

"The life of a wild animal," he tells us in italics, "*always has a tragic end.*" Perhaps so; if, but only IF, sudden destruction coming unawares to end a bright existence—Death appearing without "the painful family," "more hideous than their Queen"—is necessarily a tragedy. But the world, after all, is something more than a great slaughter-house. There is, for the humbler creation at least, a "blindness to the future kindly given," and, so far as we can judge, a keen power of enjoying the present. The blackbird is not always thinking of the sparrowhawk, the ant of the turkey, nor the turkey of Christmas. The necessity for keeping the protective sense constantly on the alert may be the very best means for keeping the faculties of enjoyment bright and polished.

"A certain number of fleas," according to David Harum, "is good for a dog. They keep him from brooding on being a dog." T. DIGBY PIGOTT.

ELEMENTARY GEOMETRY.

Elementary Geometry, Plane and Solid, for use in High Schools and Academies. By Thomas F. Holgate, Professor of Applied Mathematics in North-Western University. Pp. xi+440. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1901.) Price 6s.

THIS book covers the ground of the first six books and those parts of the eleventh and twelfth books of Euclid which are usually read; and it includes besides a discussion of the elementary properties of the simpler solid figures, the sphere, the cylinder and cone. There is also a brief appendix on trigonometry.

The introduction deals with preliminary notions and definitions, and the first chapter with triangles and parallelograms. The second chapter treats of the circle in a manner which is more direct than Euclid's, and is free from the impossible figures so bewildering to a beginner. It contains an interesting Article 204, on the principle of continuity, in which instances are given of propositions which, though very different at first sight, can by the application of the principle of continuity be harmonised under one general statement. Illustrations of this kind are most helpful and stimulating.

The third chapter, on similar rectilineal figures, contains a section on measurement, ratio, proportion and the theory of limits. As no definite agreement has yet been arrived at among teachers as to the best mode of treating this part of the subject, it is to this section that the main interest of the book is due. There is much to be said for the view of those who would definitely postpone any discussion of incommensurables to a later stage, but as it may be inferred from the book that this is not the view of the author, it will not be considered here. In order to make clear the relation of his treatment to the usual English practice, it is necessary to state very briefly what that practice is. It is usual to direct beginners to learn the fifth definition (the test for equal ratios) by heart without any adequate explanation,[1] although it rests upon ideas of extreme simplicity. It is doubtful whether one pupil in ten thousand understands the definition, though a great many are able to apply it correctly to prove two important propositions in the sixth book, viz., No. 1, "The areas of triangles (and parallelograms) of the same altitude have the same ratio as the lengths of their bases have to one another," and No. 33, "In equal circles, angles, whether at the centres or circumferences, have the same ratio as the arcs on which they stand have to one

[1] The so-called algebraic explanations frequently supplied are inadequate.

another: so also have the sectors." For the proof of these two propositions *only* is the fifth definition usually employed. All the remaining properties of proportion required for use in the sixth book are either assumed or proved (it would be more correct to say they are supposed to be proved) algebraically. Some teachers, probably a small minority, use the syllabus of the Association for the Improvement of Geometrical Teaching. This syllabus, following Euclid's line of argument, *uses the properties of unequal ratios to prove properties of equal ratios*, thus making the proofs unnecessarily artificial and therefore difficult; so that, though it is quite possible for a clever pupil to follow the reasoning in each separate proposition, it is very difficult for him to grasp the argument as a whole.

In the book under notice the fundamental definitions of the fifth book of Euclid, viz., the test for equal ratios, No. 5, the test for distinguishing between unequal ratios, No. 7, and the definition of the compounding of ratios, with which may be included the definition of duplicate ratio, find no place. And it may be conceded at once that, if these definitions are not properly explained, it is much better that they should not appear in an elementary text-book, because the beginner, to whom the simple ideas on which they rest are not carefully expounded, is far more likely to make progress in geometry with the aid of Prof. Holgate's book than with an ordinary Euclid.

The author, after defining the ratio of two incommensurable magnitudes as the limit of a rational fraction, obtained by a definite process (Art. 229), proves a general theorem on limits, viz., "that if there are two variable quantities dependent on the same quantity in such a way that they remain always equal while each approaches a limit, then their limits are equal" (Art. 230).

With the aid of this, the two propositions, Euc. VI., 1 and 33, already referred to, are proved, and also the proposition "that a straight line parallel to one side of a triangle divides the other two sides in the same ratio," Euc. VI., 2 (first part).

Taking the proof furnished of this last theorem as a type, and leaving out of it the use made of the general theorem on limits quoted above, it may be pointed out that the proof is in effect a demonstration (though some expansion would be necessary to make this clear) of the proposition that if a certain definite process be applied to the segments of each of the sides of the triangle the result will be to determine the same irrational number[1] in each case, so that this irrational number may be taken as the measure of the ratio of the two segments of each side, and that consequently these ratios are equal. With such a change the treatment would accord with modern ideas regarding irrational numbers as set forth by Dedekind in his tract on continuity and irrational numbers[2] and now generally accepted.

But when such propositions as "that if two ratios are equal, their reciprocal ratios are equal" are required (see Arts. 234, 237–240), then the proofs supplied are valid for commensurable ratios only. This change in the mode of treatment should have been clearly indicated in the text or preface. To have proved these propositions on the lines on which the treatment of the subject of ratio had been begun would soon have carried the author beyond the comprehension of those for whom his book was intended. To have proved them upon Euclid's lines would have made it necessary to add a large number of additional explanations. This, however, was the only practicable logical alternative.

The fourth chapter deals with the areas of plane polygons and with the measurement of the circle. Archimedes proved that π lies between $3\frac{1}{7}$ and $3\frac{10}{71}$ by a consideration of the regular inscribed and circumscribed polygons of ninety-six sides. The author obtains a much closer approximation, but finds only a series of values increasing up to π by using the inscribed regular polygons. The result would have been more impressive if a series of values decreasing down to π had been found as well.

The sixth chapter deals with lines and planes in space. It is a matter of opinion whether the modes of constructing the perpendicular to a plane in §§ 403 and 408 are or are not more difficult than Euclid's; but these last are so useful in Spherical Trigonometry that it seems a pity they have not had more prominence given to them than is furnished by § 406. For a similar purpose it would have been useful to give some further account of the angles between a line which meets a plane and the lines in the plane than Prop. xx. in § 449, viz., "The acute angle which a straight line makes with its own projection upon a plane is the least angle it makes with any line of that plane." It is advantageous to know, not only the least and the greatest angles between a fixed line meeting a plane and lines in the plane, but also the way in which the angle varies as the line in the plane revolves.

The statement of Prop. xxii., § 458, "that the sum of any two face angles of a trihedral angle is greater than the third angle," should be limited by inserting the word "convex" before the word "trihedral."

The seventh, eighth and ninth chapters deal with prisms, pyramids, cylinders, cones and spheres.

There are several features of interest in the book, such as the use of the principle of continuity in §§ 204, 264, 323, and the directions given in § 540 for constructing the regular polyhedra. The proofs of many of the propositions seem to be new. The work is evidently that of an experienced teacher, and is written on the lines of good class teaching, in which the teacher suggests steps in the argument to the pupil, and the demonstrations are worked out by both together. The book is calculated to arouse and stimulate those who have at heart the teaching of their subject.

MOSQUITOES AND MALARIA IN MAURITIUS.

Les Moustiques: Anatomie et Biologie. By A. Daruty de Grandpré and D. d'Emmerez de Charmoy. (Port Louis, Mauritius: *Planters' and Commercial Gazette*, 1900.)

THIS work is a contribution to the study of the Culicidæ, and principally of the genera Culex and Anopheles, of their *rôle* in the propagation of malaria

[1] An irrational number is defined as one which separates all rational fractions into two classes, an upper and a lower, such that
(1) Every fraction in the lower class is less than every fraction in the upper class.
(2) The lower class contains no greatest fraction.
(3) The upper class contains no least fraction.

[2] Translated into English by Prof. Beman. (Chicago: The Open Court Publishing Co., 1901.)

and filariasis, and of the means of guarding against them. The authors recognise in Mauritius only the types of fever quartan, tertian and æstivo-autumnal, and have proved *Anopheles costalis* to be the definitive host of their parasites in that island. Three species of Culex —*C. anxifer*, *C. albopictus*, *C. taeniatus*—were shown to be incapable of infection by parasites of human malarial fever. *Anopheles mauritianas* also appears to have no relation to human malaria. The chapters on classification, morphology, anatomy and biology add but little to the literature of these subjects. In the present state of our knowledge of the ætiology of malaria and filariasis a more careful description of the minute anatomy of the organs of the adult insect would have been extremely useful; probably difficulties in the preparation of complete and perfect sections have prevented the authors giving minute histological details. Descriptions of such important structures as the membranous portion of the pharynx, of the salivary receptacle, and of the muscles attached to them, and, in view of the importance of the recent discoveries of the presence of filarial larvæ in the labium of the proboscis, the relations and histology of this organ especially, should have claimed the attention of these naturalists. The spermatheca of the female insect is not referred to.

The authors are evidently not acquainted with the structure of the parts of the proboscis. The salivary duct is described as uniting the pharynx to the œsophagus. Careful histological preparations show that this is far from correct; the salivary duct traverses the neck and head below the œsophagus and pharynx, and, in the region of the common origin of the mouth-parts from the head, the duct opens into the salivary receptacle—a chitinous trumpet-shaped organ with a wide membranous proximal end into the middle of which the salivary duct opens itself; while the narrow distal end is applied to the upper end of a groove—the salivary canal—which runs along the whole length of the hypopharynx.

The cells of the epithelium of the stomach are described as :—(1) Large spherical cells, with protoplasm not stained by carbol-thionin, while the nuclei stain pale rose-colour and the nucleoli violet. These are said to be of lymphocytic nature. (2) Small spherical cells, with a deep violet-staining nucleus, and protoplasm which centrally stains with difficulty while the periphery is deeply stained. These the authors consider to be digestive in their functions.

The epigastric glands of the larval stage, eight in number, surrounding the anterior part of the stomach, and the dialysing tube or membrane in the stomach wall, are considered as playing an important part in the digestive functions of the carnivorous larva.

With regard to filariasis, the authors apparently found only *F. nocturna* in the blood of the people of Mauritius where elephantiasis also occurs, and they have been able to trace the complete life-history of the larval stage of this nematode in the thoracic muscles of *Culex anxifer*.

The authors do not appear to have recognised the presence of malarial parasites in the blood of native children, and hence do not refer to segregation of Europeans as a preventive measure. "Eviter les Anopheles" is their advice, and they uphold the opinions of Ross and others that, although, perhaps, absolute extermination of the insects will prove impossible, even in small areas, yet their numbers may, by the application of inexpensive and practicable means, be easily reduced to an almost harmless minimum. They rely chiefly on the use of culicicides, particularly of petroleum, and of culicifuges, such as terebinthene and naphthalene.

H. E. A.

OUR BOOK SHELF.

Disease in Plants. By H. Marshall Ward, Sc.D., F.R.S., Professor of Botany in the University of Cambridge. Pp. xiv + 309. (London: Macmillan and Co., Ltd., 1901.) Price 7*s.* 6*d.*

THIS is a very suggestive work, and the clearness with which Prof. Ward has treated a difficult and complex subject will ensure for his book a welcome on the part of the specialist, not less than that of the wider public to whom the volume is more immediately addressed.

Most treatises on plant pathology deal with the more extrinsic aspects of the matter, such as the host and the parasite, and some of them give accounts of the evil results of an unfavourable environment. But in the book before us the questions raised are discussed from a more philosophical standpoint. The effort is made to discern wherein disease itself really consists, and to ascertain the actual relations and changes involved in the transition from the healthy or normal to the abnormal and pathological condition. "Disease (not diseases) in Plants" is the title of the book, and it fully indicates the general purport of the contents.

In order to place the reader in a position to appreciate the nature of the connection between a healthy and a diseased state, the opening chapters are devoted to a consideration of the normal physiology of the plant-organs and their relations with their surroundings. Then the various disturbing influences which make for, or actually induce, disease are passed under review, and their operations as far as possible explained. The imperceptible gradations by which an organism passes from the healthy to an unhealthy condition are pointed out, and the oftentimes indirect operation of an unfavourable influence is insisted on. One is brought into closer quarters with the heart of the matter on recognising that the most injurious factors are those which operate through the metabolic processes of the plant; just as, it may be remarked, is malnutrition in the widest sense at the bottom of so many of the ills which the animal flesh assumes itself to have inherited. The interference may come through unfavourable conditions of life, or it may be more immediately traced to influences exerted by other organisms such as parasites and the like. And these considerations open the way for discussing the question of "predisposition" and examining the various avenues in this direction leading to possible remedial measures.

Of course in a work of this kind there are some views put forward which may not command universal acceptance, but they are chiefly those concerned with side-issues, and can hardly be profitably discussed within the limits of a brief notice. Enough, it is hoped, has been said to emphasise the fact that the book forms a valuable contribution to a subject of vast importance. For on the right understanding of the nature and causes of disease in plants hang many great commercial and even national interests. The annual loss incurred through the agency of disease is enormous, but the results of current work clearly demonstrate that much of this loss can be curtailed or prevented when its causes are understood and empirical remedies have given place to intelligent counteraction.

J. B. F.

Shell Life: an Introduction to the British Mollusca. By E. Step, F.L.S., &c. "Library of Natural History Romance." Pp. 414, 32 Plates, Figs. in text. (London: F. Warne and Co., 1901.) Price 6s.

COULD paper, print and pictures make a meritorious book, this would be one. The paper is of superior quality, and the print is exceptionally clear and clean; whilst the illustrations, although drawn from many sources, good, bad and indifferent, are well printed.

The thirty-two photo-process plates are excellent of their kind, their only fault consisting in the want of good arrangement in their component items and the inclusion of some objects far too minute for this method of illustration. Unfortunately there is no reference to them in the text, and the names cited on the plates do not always coincide with those given in the text.

The figures in the text are some of them very old friends, and saw service in the Rev. J. G. Wood's "Common Shells of the Sea-shore"; others are of later date and foreign extraction. Nor must we omit a word of praise for the binding and the tasteful and quaint, if not entirely appropriate, design on the cover.

It is a matter for regret, however, that the author did not make himself more familiar with his subject so that his work might have been something better than the mere outcome of industrious compilation from authorities more or less ancient. Thus he instances the patelliform as the primitive type of the molluscan shell; he is unaware of the existence of a rudimentary heart in Dentalium, and gives renewed currency to the blunder (founded originally on a mistranslation) that its embryo shell is bivalve; and so on, and so on.

In the matter of classification our author follows that of the Cambridge Natural History, which, having already been dealt with in these pages (vol. lii. p. 150), need not be further commented on here; nor shall words be wasted on the nomenclature employed, which is hopelessly out of date.

In the endeavour to confine scientific names entirely within brackets and furnish "popular" names where none such exist, the author is driven to translations, some of which recall those that once figured on the fossil fish tablets in the British Museum. As a rule derivations of names are, perhaps wisely, avoided; but we do meet with "Aplysia (from *a* and *plus*, unwashable)."

On the whole we incline to the opinion that the publishers did well to include this book in their "Library of Natural History Romance." (BV)^2.

Arithmetic. By R. Hargreaves, M.A. Pp. viii+416. (Oxford: Clarendon Press, 1901.) Price 4s. 6d.

IT is very difficult for an author to produce anything strikingly new in such a well-worn subject as arithmetic, and consequently this treatise greatly resembles two or three others of the most meritorious character. A good feature of the work is the attention which it devotes to the *theory* of arithmetic. Labour-saving processes, when long multiplications have to be performed and one of the factors possesses some particular simplicity of form, are frequently given—to the interest as well as to the advantage of the pupil.

If only our terrible system of weights and measures were replaced by the metric system, what a load of revolting and time-wasting work would be removed from the path of the English pupil! A short account of this system will be found in the present work.

Perhaps the explanation of the properties of recurring decimals is scarcely so complete and systematic as it might be. Here the use of a little algebra would do a great deal towards promoting in the mind of the pupil an understanding of the various rules for treating these decimals; and there seems to be no valid reason against the employment of algebra for such a purpose. Purely arithmetical proofs necessarily fail in generality.

There is a good section on approximative work which will be a great help to the learner. There are also sections on the square and cube root; but, with a logarithm book in our hands, the utility of arithmetical or algebraical processes for finding a cube root is more than doubtful.

The work abounds with examples, and with good hints to the pupil for shortening calculation and for choosing one mode of procedure in preference to another when two or more ways of doing a thing present themselves.

Intermediate Practical Physics. By J. B. Wilkinson. Pp. x + 154. (London: Chapman and Hall, Ltd., 1902.) Price 2s. 6d.

THIS book is for the intermediate and preliminary scientific examinations of the London University, and deals with experiments of a very simple kind. The exercises illustrate the various branches of physics, and they seem to be very suitable for beginners; but we regret that in many cases the descriptions are not accurate. Thus, in describing the measurement of the diameter of a sphere by placing it between two squared blocks, we are told to test the right-angles of the blocks by seeing whether they fit when placed on the table and then turning both blocks over. Surely this is no test. A little further on, in the account of the siphon barometer, the correction for change in density of the mercury and the expansion of the glass scale is attempted, but sadly needs revision and rearrangement. We should also like to know why the corrections for temperature are given with the siphon barometer and not with Fortin's pattern, where they must be equally important. Although many other points in the book require some correction, we think it is written on the right lines, as it aims at simplicity.

S. S.

Flowers of the Field. By the late Rev. C. A. Johns. 29th edition. Entirely rewritten and revised by G. S. Boulger, B.A., F.L.S., F.G.S., Professor of Botany in the City of London College. Pp. xlii + 926. (London: Society for Promoting Christian Knowledge, 1899.)

THE fact that this work should have passed through so many editions sufficiently proves its popularity. The present volume is an improvement on its predecessors, both by reason of the inclusion of new and valuable matter and by the excision of some that could be very well spared. The more definite and full descriptions of the species should aid in the identification of our British plants, but the illustrations still are capable of improvement. The book is, however, sure of a wide circulation amongst the large number of people who take an interest in, and desire a closer acquaintance with, the wild flowers of the country.

Correlation Tables of British Strata. By Bernard Hobson, M.Sc., F.G.S. (London: Dulau and Co., 1901.) Price 5s.

A SHORT time ago (NATURE, April 11) attention was called to the publication of Woodward's "Table of British Strata," also issued by Messrs. Dulau and Co. The present work is in some respects far more elaborate, as it comprises nineteen detailed tables ranging from Archæan to Pleistocene. The plan of the compiler is to give the subdivisions of each formation as determined in different regions in Great Britain and Ireland. Thus, to take the Cambrian, there are columns for North Wales, South Wales, Malvern Hills, Wrekin area, Nuneaton, North-west Scotland, and Ireland; and in these columns the various local divisions and their estimated thicknesses are given, together with references to original sources of information. No attempt is made to enumerate the

characteristic fossils, the leading zonal forms—*Olenellus*, *Paradoxides*, *Olenus* and *Dictyonema*—being the only fossils noted from the Cambrian system. In dealing with Ordovician and Silurian strata the graptolite zones receive particular attention, and other zonal fossils are mentioned. The full stratigraphical details relating to these systems make one feel that scant justice is done to the Devonian; but as a matter of fact our knowledge of that system is far less precise. Here, as occasionally elsewhere, a column for Continental divisions is given. In the Lower Carboniferous, Mr. Hobson starts with the Devon succession and places the Lower Culm Measures with the Coddon Hill Beds on the horizon of the Lower Limestone Shales, whereas their characteristic *Posidonomya* and *Goniatites* indicate an horizon equivalent to the Upper Carboniferous Limestone or Yoredale Series. He has not, however, ventured to indicate zones in the Carboniferous, although materials have been gathered in the neighbourhood of Bristol as well as in northern counties, to which reference is made in the preface. Here and there we would suggest a greater uniformity in method: for instance, the Ammonite zones of the Lias are noted under the names *Ægoceras*, &c.; those of the Inferior Oolite are noted as *Parkinsoni* zone, &c.; and those of the Cretaceous rocks as *Ammonites lautus*, &c. The most difficult correlation is, doubtless, that of the Pleistocene, and here the student may well pause, for the "Upper Boulder Clay" of different areas is not to be regarded as contemporaneous. Indeed, the compiler in his preface remarks that "strata named on corresponding horizontal lines cannot, in some cases, be considered to be of corresponding age"; and the student will do well to bear this in mind.

The work is issued as one of the museum handbooks of the Manchester Museum, Owens College. It cannot fail to be of great service for reference to geologists in general. It bears evidence of the most painstaking care and of wide research up to the date of publication; and we feel confident that the labour will be appreciated.

Die Partiellen Differential-gleichungen der mathematischen Physik. By Heinrich Weber, based on Riemann's lectures. Vol. ii. Pp. 527. (Brunswick: Fried. Vieweg and Son, 1901.)

IN reviewing the first volume of this book (NATURE, vol. lxiii. p. 390) it was pointed out that owing to the great advances in mathematical physics which have taken place in the forty years since Riemann's time, Prof. Weber had found it necessary, instead of merely issuing a revised edition of the well-known "Partielle Differentialgleichungen," to write practically an entirely new book. The present volume, which is written much on the same general lines as the first, is divided into five parts. The first contains the more important properties of hypergeometric series and their application to the theory of linear differential equations. The second part, dealing with conduction of heat, is much after the lines of Riemann's original treatment, and treats mainly of conduction in one dimension and conduction in a sphere. The third part is devoted to theory of elasticity and vibrations, the torsion problem being included in the former subject, and vibrations of strings and membranes in the latter. Electrical oscillations come next in order, and the last part consists of hydrodynamics and propagation of plane and spherical sound-waves, including Riemann's own theory of sound-waves of finite amplitude.

Seeing that a whole volume might be written on any one of these branches of mathematical physics and still leave many interesting points untouched, the treatment in the present book is necessarily but fragmentary in character, but Prof. Weber is to be congratulated on the number of points which he has been able to touch in the limited space of about 500 pages. At the end is an index to both volumes. G. H. B.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Total Solar Eclipse of September 9, 1904.

As inquiries have already been addressed to me as to the practicability of observing this eclipse, which passes across the Pacific Ocean (see "Nautical Almanac," 1904, pp. 487–490), perhaps I may be allowed, thus early, to communicate, through your instrumentality, the information I have collected on the subject.

The Walker Islands, which appear on some maps of the locality in the position 149° W., 4° N., would have been, if they existed, very favourably situated for the observation of the eclipse. But recent surveys have shown conclusively that they do not exist.

Kingman, or Caldew, Reef, 162° W., 6° N., is also favourably situated, but is stated in the Admiralty Sailing Directions to be partially dry at low water only.

Palmyra Island is placed by the most recent survey in the position 162° 6′ W., 5° 52′ N., and is thus a little too far south to be available. Proceeding westwards, the next group of islands encountered is the Marshall Islands. But even the most easterly of the group on the track of the eclipse—Aur—is too far west for our purpose, as the middle of the eclipse occurs there shortly after sunrise.

It appears that there is no island conveniently placed for the observation of this eclipse, and astronomers must wait for the total eclipse of the following August, which will afford ample opportunity for observation in Canada, Spain and North Africa.

A. M. W. DOWNING.

The Dilution of Acetylene for Heating Purposes.

YOU have been good enough on one or two previous occasions to give me a few lines in your columns on questions connected with acetylene for heating, and as this use of the gas is extending and will undoubtedly have a much wider extension in the near future, perhaps you will renew your courtesy in this matter.

In country places for domestic and laboratory purposes, more especially with the advance of electricity and decline of coal gas for lighting, the field for acetylene for heating is very large and has so far met with strangely little consideration. The combustion of a gas containing 92 per cent. of carbon successfully in a Bunsen burner is not more easy than its combustion to produce a trustworthy luminous flame. The chief difficulty from which we suffer in the former matter is the relatively high pressure under which the gas must be burnt. No one has yet devised a Bunsen burner which will give a flame large enough for ordinary working purposes under a pressure of less than six inches of water, and even then luminosity is not entirely banished, practically no margin being left for incorrect adjustment of the burner. The pressure is objectionable, it puts the gas fittings to a severe test in the matter of leakage, it is much more than is required for lighting and has to be specially arranged for in many generators, and in those of the automatic class it involves more "after gas," necessitating larger storage capacity. The fine orifice of the jet and the necessarily narrow tube with its accompanying increased internal friction and the large injecting power essential, all make high pressure a necessity. That this luminosity trouble is partly a matter of temperature can be easily shown by heating the tube of a non-luminous Bunsen, or pouring water on to the tube of one showing luminosity, the effect being very striking, and some improvements on these lines have suggested themselves and are efficient as far as they go. We want, however, to attack the root of the matter and dilute our acetylene to begin with, and this dilution would not be altogether objectionable from a lighting point of view. Lighting burners at present generally inject some air and can only themselves be regarded as on the verge of respectability; quite an absurdly small amount of benzene vapour is sufficient to put out of temper the lighting burners now on the market. Such dilution would give them the margin for bad usage which makes so much for success in practice, even though wasteful in theory.

In seeking a diluent, one turns naturally first to metallic carbides other than calcium, with the idea of finding a commercially possible carbide which will give methane or hydrogen on decomposition with water and could be blended with calcium carbide by the manufacturer to suit, if necessary, various requirements, when we should once more see the early attempts to use for lighting the ordinary household Bray burner repeated with success. Manganese carbide is stated to be easily formed, and by Moissan to be decomposed by water yielding equal volumes of methane and hydrogen, hausmanite (presumably prepared by heating pyrolusite) being recommended. An attempt on my part to make a few grams, though it is true that the amperes at disposal only just reached double figures, failed as regards any gas produced, although reduction undoubtedly took place. I should not presume to quote so insignificant an experiment had not the manager of the Acetylene Illuminating Co., who courteously gave me an interview some months ago, told me that the Company's experiments on this carbide (and science is indebted to the Company for a great many researches, which I hope it may see fit to publish) had not led to the production of a carbide at all easily decomposed by water. I suggested the use of manganese mud as being easily obtainable, very free from silica as compared with pyrolusite, not so highly oxidised, and in a very fine state of division, and I hope that the Company may see fit to try it. Among other carbides, that of aluminium seems to offer attractions for commercial investigation, and although magnesium carbide cannot be prepared in the electric furnace alone, I do not think that dolomite as a substitute for pure carbonate of lime has been experimented upon.

Failing a suitable carbide for dilution, will not some organic chemist come forward with a bye- or waste product which will decompose in the presence of hot caustic lime produced in the generator, with, if not the production of methane, hydrogen or carbon monoxide, at least some indifferent gas, such as nitrogen or carbon dioxide?

Investigations are wanted as to the amount of diluent required to banish luminosity under some standard conditions. I can only speak at present of carbon dioxide; a Bunsen burner consuming one cubic foot of acetylene per hour under six inches water pressure, showing a fully developed luminous zone rather greater in diameter than the sum of the widths of the non-luminous zone on either side, requires a supply of carbon dioxide at the rate of 0·15 cubic feet per hour to destroy completely this luminosity. A. E. MUNBY.

Felsted, November 1.

Magnetic Iron Ore as a Material for Concrete Blocks.

THE account of harbour works in NATURE of October 24 (p. 639) causes me once more to draw attention to the great advantage which would be gained by the use of magnetic iron ore as a material for concrete blocks. If magnetite is used instead of ordinary rock in the shape of fragments, and magnetic sand or ilmenite sand instead of common sea sand, concrete blocks can be obtained which have all the strength of the ordinary concrete blocks and which weigh, when immersed in water, exactly twice as much as the ordinary blocks. Such an increase in weight makes the magnetic blocks far superior as regards resistance to the waves. Work constructed with magnetic blocks will stand when other work will be destroyed. This superior effect of magnetic blocks is quite independent of the size of the blocks. The artificial increase of the size of ordinary concrete blocks is mentioned as a means of increasing the power of resistance, but there are certain to be some objections to this method, and if the great masses are ruptured after the rusting away of the cases, portions may give way. It is therefore better and more convenient to use the superior composition. As regards the expense, it may be mentioned that to obtain a good effect it is only necessary to use magnetic blocks for the most exposed spots of a dam, and more in the nature of a surface coating. There are immense natural deposits of magnetite, also of titanium ore, which latter is not of value for steel making, and it would surely be possible to obtain the necessary quantities in Scandinavia, or if for harbours in the East, then there would be inexhaustible supplies in southern India not too far from the coast. It has been argued that the iron ore would decay on exposure to sea water and that it would injure the cement. This may be true for inferior iron ores, but not for rich, pure magnetite and ilmenite, as I have proved by direct experiments. I have exposed fragments of magnetite to the action of filtered sea water in clean glass jars where every trace of decomposition would have been detected, but though I continued the test for a year the specimens stood the test very well. Moreover, I made sample blocks with Portland cement and subjected them to crushing tests, which showed them to be perfectly satisfactory as regards strength.

H. WARTH.

The San Clemente Island Goat.

LAST summer, at San Pedro, California, I was shown a goat which had just been brought over from San Clemente Island. Mr. Müller, the owner of the animal, told me that the goats of that island, running practically wild since the unknown date of their introduction, were all alike, constituting an easily recognisable race. The animal was quite reddish, about the colour of a red deer; front of face black; a pale (reddish) stripe down each side of nose, and enclosing the eye; cheeks black; chin light; ears blackish above; neck and anterior part of body strongly suffused with black. The light facial stripes were particularly distinct.

The Santa Catalina Island goats, I was informed, are variously coloured. This is doubtless due to the fact that Catalina is a popular resort, and fresh animals are frequently introduced.

East Las Vegas, New Mexico, U.S.A., October 27.

Food of Grass Snakes.

MAY I say, in defence of Dr. Gerald Leighton (see p. 625), that on two occasions I have found mice inside grass snakes. The first case was on a moor near Parkstone, Dorset, where on opening a smallish snake we found a mouse only partly digested. The other case occurred here last year, when I found a small shrew in a large grass snake. Also with regard to them swallowing birds, I have three times found birds inside them. In each case they were young ones; two were probably young larks (they were both in one snake), and the other was a young robin. C. M. ROGERS.

Wellington College, Berks, October 28.

THE OBSERVATORY OF MONT BLANC.[1]

IN observing the physical features of the Alpine regions, M. Vallot and the several members of his family show a devotion that no discouraging circumstances can damp, and an energy that rises superior to the inclemencies of the weather and the loneliness of the situation. His original observatory, constructed after much labour and in spite of many difficulties, was found to be in an unfortunate position, owing to the accumulation of snow with which neither labour nor expense could efficiently deal. Without hesitation this construction is abandoned, and in the light of greater experience a fresh site is selected and a new observatory built, where, from the peculiarity of configuration, snow cannot collect and interfere with the progress of the work. This building, constructed in 1898, admirably fulfils its purpose, and here, at an altitude of 4358 m., among the eternal snows, M. Vallot and his band of energetic labourers pursue their scientific avocations. These are sufficiently various, and in the present volumes we have the result of three distinct investigations, one dealing with the influence of barometric pressure on the chemical action of solar light, another on the velocity of water in streams and under glaciers, while the last gives an account of experiments undertaken with the view of detecting the rate and character of glacier motion.

Of the first of these discussions it is sufficient to say that the author aims at a re-examination of the adequacy of the formula found by Bunsen and Roscoe in similar researches, wherein occurs a numerical coefficient

[1] "Annales de l'Observatoire météorologique physique et glaciaire du Mont Blanc." Publiées sous la direction de J. Vallot, Fondateur et Directeur de l'Observatoire. Tome iv. Pp. ix + 189. Tome v. Planches du Tome iv. (Paris: G. Steinheil, Editeur, 1900.)

depending on the height of the barometer. M. Vallot adopts the same form of expression, but unfortunately does not give the means of comparing his numbers with those found in the earlier investigation. Moreover, the methods employed are not quite the same, and a slight difficulty arises from the selection of a silver salt whose maximum effect is not exhibited at the same part of the spectrum as in the case of Bunsen and Roscoe's inquiry. Making allowance for a slight discrepancy in this respect, we gather that while Bunsen and Roscoe claimed that 59 per cent. of the solar light was lost by transmission through the atmosphere, M. Vallot finds that only 40 per cent. is so lost. Treating the sensitised paper in such a way as to make the maximum sensibility coincide with the optical maximum, M. Vallot finds the coefficient of atmospheric transmission to be 0·826, corresponding with the mean of the values found by Bouguer, Leiden and Trépied. While the agreement quoted is quite satisfactory, we miss any reference to the work of Captain Abney on the Faulhorn (2683 m.), of Dr. Muller at the Etna Observatory (2944 m.), or of Prof. Langley on Mount Whitney (3513 m.). These latter authorities have all found a rather larger transmission coefficient than others who have worked nearer the sea level, and the greater altitude of the Mont Blanc Observatory might have afforded some explanation. Doubtless if the object be to inquire into the effect of the variation of a particular factor, there is an apparent advantage in conducting the observations in such a way that that factor is most materially affected, but the advantages can be considerably discounted by the extra difficulties introduced by the remoteness of the situation and other causes, and though M. Vallot and his assistants have striven manfully with the difficulties, greater weight would attach to his results if the observations had been more frequently repeated, though at a lesser height and with a smaller diminution of the barometric pressure.

The means employed for discussing the relative velocity of water in streams and torrents is discolouration of the water by means of a powder (fluorescin), which on dissolving rapidly gives rise to a green tint, and then observing the time at which the discoloured water arrives at a distant station. M. Vallot very properly insists upon the necessity of a sufficient expenditure of the powder, which can be determined experimentally according to conditions varying with the quantity of outflow that passes a given point, the colour of the water, &c. Observations made in this way do not permit of very great accuracy owing to the tendency of the coloured water to spread itself according to the character of the channel over which it passes, but when it is a question of determining the velocity in a subterranean channel, under glaciers, it is difficult to see what better means could be devised. M. Vallot has confined his attention mainly to the effect of the slope of the river bed on the rate of flow, and concludes that this is most rapid when the incline is about three in a hundred. As the slope increased, contrary to his expectation, the rate as measured horizontally, diminished. From this he concludes that the onward rush of water along steep ravines is more apparent than real. When the incline is very steep the effect is to hollow out the bottom, giving rise to great irregularities in depth which produce eddies and tend to stop the hurrying progress. It is therefore the mean velocity with which M. Vallot is concerned, and the distances measured vary from 1000 to 4000 m. The maximum velocity observed in the unconfined stream is 2·25 m. per second, and for a subterranean current of the same slope the progress is about one half of this quantity. The same ratio obtains between open streams and sub-glacier currents, whether the horizontal or vertical velocity be measured.

But the particular investigation to which M. Vallot has devoted the greatest attention is the movement of the glacier, Mer de Glace, in its various parts. Here the author enters into a very difficult inquiry, and it would be surprising if some of his results did not differ from generally received opinions. As a contribution to a more complete investigation the study made by M. Vallot is no doubt valuable, and much of his work, such as the difficult triangulation of the Mer de Glace, will be appreciated by later observers. But a complete theory of glacier movement is not to be derived by a study, however minute, of a single glacier in the space of a few years. An international commission under M. Forel has been at work for a considerable period and is probably still collecting data which show that the problem possesses many perplexing variations, not the least difficult being the evidence of periodicity in glacier movement connected with some obscure law that appears to affect the general climate of the earth. During the eight years that M. Vallot has been at work on this subject, he claims to have established the following prominent facts, which undoubtedly have reference to the particular phase of the motion which obtained in the period to which his observations have reference. We regret that it is impossible to enter with minuteness into the character of the evidence by which his conclusions are supported, but they may be briefly summarised thus: (1) That the progress of the glacier throughout the year is constant, the summer does not hasten nor does the winter witness any abatement of the uniform progress. Changes of incline of the bed on which the glacier moves will always explain any observed variation of velocity. (2) That the uniformity of the velocity in all seasons is opposed to any theory of regelation, or, indeed, to any explanation in which changes of temperature play a part. (3) That the movement of the glacier does not partake of the character of a viscous fluid, the whole moving as one piece. M. Vallot thus sums up the result of his long and arduous labours, which have been pursued under great difficulties with considerable skill and over a large area. We can only hope that the experience he has gained will be still longer employed in this species of investigation. "La conclusion de ce travail est que *la progression des glaciers est causée par le glissement de la masse, sous l'action de la pente du lit, aidée par la poussée des parties postérieures.* La pesanteur seule parait être en jeu, à l'exclusion de toute action calorifique."

GEOLOGY AND METEOROLOGY.

THE subject of climatic changes has always been of absorbing interest to geologists, and they have been perhaps more puzzled to account for the occurrence of plants of temperate or even subtropical character in Arctic regions than for the occurrence of wide-spread Arctic conditions in temperate regions. To explain these changes in the northern hemisphere, the alterations in the distribution of land and water and consequent influence on the Gulf Stream, the modification of the internal heat of the earth, changes in the position of the earth's axis, variations in the amount of heat given off by the sun, the eccentricity of the earth's orbit, and even fluctuations in the amount of carbon dioxide in the atmosphere, have individually or collectively been invoked. The influence of ocean currents, as modified either by the elevation of a tract of islands to form a continental area or by the total or partial submergence of a continent, has naturally been regarded as of very great importance. Moreover, the effect which such changes would have on winds has not been neglected, although their local influence has not been fully realized.

The apparently wide extent of tropical and subtropical climates during past epochs, with evidence of progressive diminution in temperature in later Tertiary times, has been held to be due to astronomical rather

than geographical causes. According to M. Eug. Dubois[1] one obscure enigma is that relating to the glacial episode which has been recognised in parts of India, Australia and South Africa in Permo-Carboniferous times. In those subtropical regions the débris from snow-clad mountains had been able to reach sea-level and be commingled with organic remains of almost tropical character. Other evidence, however, tends to show that there was no general lowering of temperature in this ancient epoch, but that there must locally have been mountains of considerable altitude, and that meteorological conditions were favourable to the development of huge glaciers. So also in the case of the far earlier pre-Cambrian period, during which it is believed that glaciation occurred. In connection with the phenomena M. Dubois discusses the evolution of the sun and the various influences affecting radiation of heat, maintaining that the general evidence of higher and more uniform temperature over the earth's surface prior to middle Tertiary times is well established, and is not interfered with by evidences of extensive though restricted glaciation.

In drawing attention to the influence of winds upon climate during the Pleistocene epoch (*Quart. Journ. Geol. Soc.*, August 1901), Mr. F. W. Harmer has opened up inquiries of considerable and far-reaching interest. Remarking that seasons abnormally warm or cold, rainy or dry, may be caused by the prevalence of particular winds, though the course of the oceanic circulation remain the same, he justly remarks that permanent alterations would equally result were the direction of the prevalent winds permanently changed.

Having attentively studied the causes and influence of areas of high and low pressure, he concludes that the climate of the northern hemisphere could not have been wholly cold during any part of the Pleistocene epoch, and that consequently the period of maximum glaciation in North America could not have coincided with that which affected the British Isles.

Regions covered by ice would have been to a greater or less extent anticyclonic at all seasons, low pressure systems prevailing elsewhere. The northerly winds on one side, either of a cyclonic or an anticyclonic centre, are the necessary equivalent of the southerly winds on the other, the direction in the northern hemisphere in the case of the anticyclone being like that of the hands of a watch, and in the case of a cyclone in the opposite direction.

Thus the effect of the anticyclone of an ice-sheet extending eastward from Greenland, over Great Britain, Scandinavia, and Northern Europe, would have been to change the prevalent alignment of the low-pressure system of the North Atlantic, producing warm southeasterly winds in Labrador and New England during the winter, instead of the northerly winds now prevalent there. The alteration in the direction of the winds would have tended, moreover, to divert the warm surface-currents of the North Atlantic from the European to the American coast.

It is admitted by Mr. Harmer that the maximum glaciation of Great Britain could only have taken place at a time when the Icelando-British channel was closed, either by an elevation of the submarine ridge connecting those countries or by its being blocked with ice. Thus, although the winds have naturally a most powerful influence, which he has done good service in pointing out, he is led to consider that to differential earth-movements of elevation and subsidence in different parts of the northern hemisphere may have been due the suggested shifting of glacial conditions from one side of the Atlantic to the other, and the alternation of glacial and interglacial periods in the eastern and western continents. In this way the milder periods which locally prevailed at intervals during the Pleistocene epoch would be attributed to meteorological and geographical rather than to astronomical causes.

[1] "Les Causes probables du Phénomène paléoglaciaire permo-carboniférien dans les basses latitudes." *Archives Teyler*, vii., Partie 4. (Haarlem, 1901.)

ANIMAL PHOTOGRAPHY.[1]

THE advantages of photography as compared with wood-engraving for the illustration of works on natural history are in many ways so great that any attempt to perfect and popularise the methods in use should be heartily welcomed. Quite apart from artistic effect, the great superiority of photography is that it ensures absolute accuracy, and, when living animals are the subjects, shows them in natural attitudes. In wood-engraving there are several sources of error which only too frequently make themselves apparent. In the first place, the draughtsman may make a blunder. But too often it is the engraver who is in fault, very frequently from mistaking the nature of some feature in the drawing he has to reproduce. For example, the author of the volume before us calls attention to a curious engraver's error in a well-known popular work, where, from some misconception, the mouth of a stickleback appears in a totally wrong position.

Such errors are, of course, impossible in photographs and photogravures. Nevertheless, photography has

FIG. 1.—Hedgehog.

certain disabilities of its own in regard to animal portraiture. A trained zoological draughtsman, whose object should be to produce a *characteristic* rather than an *artistic* picture, always takes care to draw his subject in a position which will show to the best advantage its distinctive features, whether of form or colour, and for this purpose he generally consults the specialist for whom the sketch is undertaken. The photographer, on the other hand, is usually content to "snap" the animal he has in hand in any effective pose, with the too frequent result that his picture, from a zoological point of view, has comparatively little value. That is to say, the features by which alone the affinities of the animal can be decided are either not shown at all, or are but imperfectly displayed.

One of the main objects of the present work appears to be to instruct photographers how to avoid these effects

[1] "Photography for Naturalists." By D. English. Pp. 132. Illustrated. (London: Iliffe, 1901.) Price 5s. net.

As a case in point, the author takes the natterjack toad. "There are three particular features about the natterjack toad," he writes, "which distinguish it from the commoner variety. It has a yellow stripe down its back, its hind feet are not webbed, and it has a peculiar running method of progression. A really good illustration of this toad would show these three distinctive features. A photograph might easily be produced which would show none of them—a side view, for instance, of the toad sitting still—and such a photograph would probably be the one taken by a photographer who had not troubled to make himself acquainted with his subject."

The author then proceeds to show the methods necessary in order to procure the desired results. Elsewhere he states that for photography of this description the only satisfactory way is to keep the animals whose portraits are desired in confinement for some little time, when they soon become sufficiently tame not to mind the approach of the artist with his camera. It will, of course, be obvious in this connection that the photographer must either be a good practical naturalist himself, or that he must consult someone duly qualified to point out the characteristic features of the animals about to be taken.

Not less important than the display of an animal's distinctive structural peculiarities is the reproduction of its characteristic attitudes. In this respect nature fortunately comes to the artist's assistance. "Living creatures," as the author truly observes, "adopt their characteristic attitudes more frequently than any others. The photographer has, therefore, to learn which attitudes his subjects most frequently adopt, and should endeavour to perpetuate them in his store of negatives."

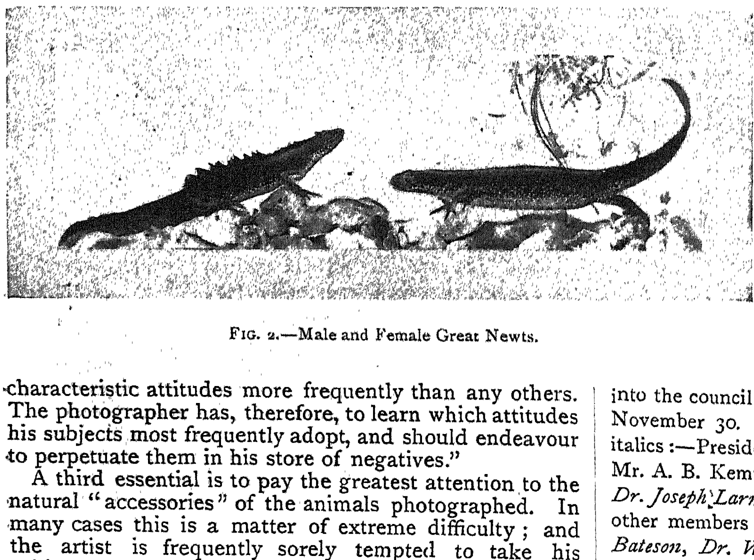

FIG. 2.—Male and Female Great Newts.

A third essential is to pay the greatest attention to the natural "accessories" of the animals photographed. In many cases this is a matter of extreme difficulty; and the artist is frequently sorely tempted to take his subject when in a favourable pose amid incongruous surroundings. Should this course have to be taken—and in some cases it is almost unavoidable—the author advises blocking out the animal and making a fresh negative with a suitable background.

Mr. English is careful to distinguish animal photography of the above nature from what he terms "stalking" photography, when the animal is approached stealthily in its native haunts with the camera, or the camera is concealed in a suitable position to await its arrival. And he renders full justice to the excellent results which have been obtained by the Messrs. Kearton in this branch of the subject.

In the main the author deals with British animals, of which he gives some exquisite pictures. Two of these, by the courtesy of the publishers, we are enabled to reproduce, so that our readers can judge for themselves as to their merits. While it is no doubt of the highest importance to have a large stock of life-like portraits of our native animals, the number of photographers who labour in this field will probably ere long produce a sufficiency. For scientific zoology the portraits of rare foreign animals are still more essential; and in a future edition it may be hoped that the author will see his way to urging his fellow-workers to take up this part of the subject in real earnest.

A large portion of the work is, of course, devoted to the *technique* of the subject; but this we may well leave to the consideration of practical photographers.

The author has done good service in endeavouring to impress on his fellow-workers the importance of producing animal portraits which shall satisfy the requirements of zoologists, and we sincerely trust that his efforts to promote improvement in these matters will not be in vain. The book should be in the hands of every photographer as well as of every naturalist. R. L.

NOTES.

THE Royal Society's medals have this year been adjudicated by the president and council as follows:—The Copley Medal to Prof. J. Willard Gibbs, For. Mem. R.S., for his contributions to mathematical physics; a Royal Medal to Prof. William Edward Ayrton, F.R.S., for his contributions to electrical science; a Royal Medal to Dr. William Thomas Blanford, F.R.S., for his work in connection with the geographical distribution of animals; the Davy Medal to Prof. George Downing Liveing, F.R.S., for his contributions to spectroscopy; and the Sylvester Medal to Prof. Henri Poincaré, For. Mem. R.S., for his many and important contributions to mathematical science. His Majesty the King has been graciously pleased to approve of the award of the Royal medals. The medals will, as usual, be presented at the anniversary meeting on St. Andrew's Day (November 30). The Society will dine together at the Whitehall Rooms on the evening of the same day.

THE following is a list of those who have been recommended by the president and council of the Royal Society for election into the council for the year 1902 at the anniversary meeting on November 30. The names of new members are printed in italics:—President, Sir William Huggins, K.C.B.; treasurer, Mr. A. B. Kempe; secretaries, Sir Michael Foster, K.C.B., and *Dr. Joseph Larmor*; foreign secretary, Dr. T. E. Thorpe, C.B.; other members of the council, Prof. H. E. Armstrong, *Mr. W. Bateson*, *Dr. W. T. Blanford*, *Prof. F. O. Bower*, Mr. C. V. Boys, *Prof. W. Burnside*, *Prof. W. W. Cheyne, C.B.*, *Prof. G. C. Foster*, Prof. W. M. Hicks, *Mr. Frank McClean*, *Prof. H. A. Miers*, *Sir John Murray, K.C.B.*, Prof. J. Emerson Reynolds, Dr. R. H. Scott, Prof. C. S. Sherrington, and Mr. J. W. Swan.

ON November 24 a medal will be presented to M. Berthelot, in the large amphitheatre of the Sorbonne, to commemorate his services to science. M. Berthelot's activity during more than fifty years has been extraordinary, and there are no branches of chemistry on which he has not made his mark. His last publication is "Les Carbures d'hydrogène," a work in three stately volumes, comprising an account of his labours on these compounds during the last half-century. To mention only some of M. Berthelot's achievements, his researches on the synthesis of the natural fats, his discovery of polyhydric alcohols, his work on explosives, on the fixation of nitrogen by plants, his long investigations in the domain of thermal chemistry, and the contributions which he has made to the history of chemistry, constitute a record of work which, it is not too much to say,

has not been equalled since the time of Berzelius. The presidents of the Royal and the Chemical Societies have been asked to be present to represent English science, and the President of the Republic will do honour to this eminent man of science by presiding at the celebration.

THE list of birthday honours includes the name of Prof. A. Pedler, F.R.S., Director of Public Instruction, Bengal, who has been made a Companion of the Order of the Indian Empire.

PROF. A. FISCHER DE WALDHEIM, the director of the Botanic Garden at St. Petersburg, has just commenced the publication of a periodical *Bulletin* of the Gardens.

THE Imperial Academy of Sciences of Vienna has received intelligence of the botanical expedition in Brazil, from its chief, Prof. R. von Waldheim, down to September 10, from São Paulo. The rivers Rio Branco, Rio Mambu, and Rio Aguapihy, flowing through an almost unexplored country, had been navigated in canoes; and large consignments have already been sent to Vienna in the form of living plants and roots, herbarium specimens, preparations in spirit, woods, fruits, and economic products.

WE have received from Major Ross the "First progress report of the campaign against mosquitoes in Sierra Leone" (Liverpool School of Tropical Medicine, *Memoir* v. part i.), in which is detailed the methods of procedure and the results up to date of this interesting attempt to reduce the numbers of mosquitoes in a district. The works carried out include the removal of rubbish, especially empty tins and broken bottles, which form breeding places for Culex and Stegomyia (the supposed yellow-fever host), and the filling up and drainage, or brushing out and treating with crude petroleum, of the puddles which harbour Anopheles. Dr. Taylor, who is in charge of the expedition, writes that it is now (September 28) difficult to find Anopheles, Stegomyia is getting very scarce, and Culex is only seen now and again. Dr. Daniels, of the London School of Tropical Medicine, gives testimony to the same effect in a report at the end. The expedition is intended to be an object-lesson in the manner of ridding tropical towns of mosquitoes by drainage and cleaning, and has been financed by private munificence.

ROPE railways have for some time been in use for the conveyance of iron ore and stone in districts where, owing to the nature of the country, ordinary railways would be impracticable. One of the latest examples of these has recently been constructed in Ireland between Ballinphellic and Ballinhassig by the Cork, Bandon and South Coast Railway Company. It is intended for the conveyance of bricks from the works of the Cork Brick Manufacturing Company, situated about eight miles from Cork. The line is four miles in length and has a transporting capacity of twelve tons per hour. There are 126 buckets, which travel at the rate of four miles an hour, each holding 3½ cwt. The rope is of steel, and there are forty-three supports consisting of steel trestles, the height of which is sufficient to allow the buckets to travel overhead clear of all obstructions. The loads automatically take on and leave the cables at the stations without any separate coupling operations. The line is worked by a stationary engine, and it requires 12 h.p. to drive the rope. The cost of transport of bricks to Cork has been reduced from an average of 18*s.* per thousand to 5*s.*

IN the Swedish journal *Jernkontorst*, a description is given by Mr. G. F. Heindenstam of the conversion of the wood waste and sawdust from the saw-mills in that country into charcoal. The waste pieces of wood cut off in the conversion of the logs are passed through rolling-mills designed for drying out the greater part of the moisture and reducing the wood to the form of sawdust. This is then passed on to heated presses and the carbonising apparatus. In these the liquid bye-product is distilled and the solid matter converted into briquettes. A plant consisting of light carbonising apparatus can deal with 9000 tons of waste wood and sawdust, from which 6000 tons of charcoal briquettes are made, the remainder being used as fuel for driving the machinery. These yield 2006 tons of charcoal, having a market value of from 2*l.* 5*s.* to 3*l.* 6*s.* per ton, besides 530½ tons of tar, 300 tons acetate of lime, and 45 tons of methylic alcohol and acetone. The total yield from these is 11,487*l.*, the cost of conversion being 7661*l.*, leaving a profit of 3826*l.* after allowing 2550*l.* for the value of the waste wood and sawdust, and 10 per cent. on a capital of 16,666*l.*

A PAPER has been contributed to the Vienna Academy of Sciences by Prof. J. M. Pernter on polarisation of light in turbid media, considered in reference to the colour of the sky. The author has observed the polariscopic effects and the relation of the polarisation to the colour in various emulsions of mastic in water, and a comparison has been made between these effects and those observed in the light of the sky. He finds that the two phenomena are in close agreement, and an experimental test is thus afforded of Lord Rayleigh's theory of the colour of the sky.

IN connection with the Austrian deep-sea expedition a paper has been published by the director, Herr Th. Fuchs, dealing with the character of the deep-sea fauna of the Red Sea. In spite of the prevailing high temperatures even at the greatest depths, the fauna is entirely of the character of a deep-sea fauna and resembles that of the open ocean. The deep-sea fauna, considered both as a whole and in regard to its individual species, shows considerable resemblance with the fauna of the so-called "Badner Tegel." Lastly, the peculiar fauna begins at a depth of about 200 metres, although the temperature at this depth is about 23° C., and is sufficiently high to allow of the growth of coral reefs.

VAN DER WAALS'S equation was undoubtedly an important step in obtaining a more approximate representation by a mathematical formula of the isothermal lines of fluids than was given by Boyle's law or similar formulæ. The further modifications proposed by Clausius, Tait and others, including, recently, Amagat, all tend to show that such formulæ are at best to be treated as mere approximations. The next step in advance, consisting in the expression of the equation of state of gases by means of series, forms the subject of a paper, by Dr. H. Kamerlingh Onnes, in the *Communications* from the Leyden Physical Laboratory, No. 61. Various forms of series were tried, and the most convenient was found to be an expansion of pv in descending powers of v. For the coefficients of these powers, which are, of course, functions of the temperature, series involving the temperature and its reciprocal as well as exponential functions of the reciprocal of the temperature were chosen. A closely allied subject, namely the precise isothermal of hydrogen at 20° C. up to 60 atmospheres, is dealt with by Mr. J. C. Schalkwijk in the preceding number of the *Communications*.

THE eleventh volume of the *Deutsches Meteorologisches Jahrbuch*, by Prof. Paul Bergholz, contains the meteorological observations of the town of Bremen for the past year. The volume is divided into six sections, the first two of which deal with the hourly and daily readings of the various meteorological instruments throughout the year, and the third with the results from the different rainfall stations for the same period. Part iv. contains the mean values of the readings of the self-recording instruments for the years 1896–1900 and 1891–1900, while part v. includes similar information from observations made three times a day. Of perhaps the greatest interest is the sixth

and last section, in which are brought together the results of the meteorological observations since they were commenced. Thus we find that the series for temperature commenced in the year 1803, that for rainfall in 1830, and pressure and humidity in 1876. The mean values are given in a very convenient form, being arranged according to intervals of a month, year, five years and ten years. There are also numerous other tables in which maxima values, minima values, temperature for each season of the year, number of frost days, &c., are separately dealt with. The volume closes with a table showing the mean values for the whole period of observation of all the meteorological elements for each month of the year, the mean temperature for every day of the year, and a set of curves illustrating many of the variations mentioned above and showing many of the mean daily variations.

THE International Aëronautical Committee have published their complete account of the results of the manned and unmanned balloon ascents which took place on November 8, 1900. The work contains the original observations, together with those taken at mountain stations, and special cloud observations on the day of the ascents. Dr. Hergesell has discussed the observations of each ascent with reference to barometric pressure, temperature and wind, and has shown on two charts the distribution of pressure and temperature at the sea level and surface of the earth respectively and at a height of 5000 metres. Great variations of temperature were exhibited in different localities, even up to the highest strata of air; the coldest districts lay in the north-west and the warmest in the south-east of the continent. At an altitude of 5000 metres, the temperature over Paris was about $-20°$ C. and over Vienna, $-11°$. The isotherms at 5000 metres run from S.W. to N.E.; that of $-10°$ extends from the north of the Adriatic to Moscow; that of $-15°$, from the south-west of France, across Germany and the Baltic to St. Petersburg, and those of $-20°$ and $-25°$ take a more northerly course, while over Ireland the air is cooled to $-30°$. The isobars at the above-mentioned altitude, like the isotherms, run generally from S.W. to N.E.; the pressure is lowest over the British Islands and highest over the S.E. of Europe. The wind velocity is best shown by the manned ascents; from the observations taken by Dr. Berson, the velocity rose from 8·3 metres per second at 1600 metres to 11·2 metres per second at 2300 metres, and he estimates that at altitudes above 6000 metres the velocity would be about 16 metres per second. The ascents were mostly made during anti-cyclonic conditions, and an inversion of temperature was generally observed, especially after reaching the limits to which the ground fog extended.

WE have received from Messrs. Isenthal and Co. a well-illustrated catalogue of electric heating and cooking appliances, which shows that this branch of electrical industry has been very fully worked out. It cannot be claimed for electrical heating that it is very economical, but its superior cleanliness and convenience are recommendations that are sure to lead in the course of time to its widespread use. A point strongly in its favour is that heat need only be generated at the time and the exact place at which it is required; an electrical cooking range can be shut down when not needed much more easily and completely than a coal fire. It is impossible to estimate the gain in cleanliness and healthiness which would result from a general adoption of electrical in place of coal or gas heating for domestic purposes, but the advantage is sure to be realised sooner or later, just as it is being realised in electric lighting, and we may hope in time to have a fogless London as a result. At present electric lighting companies have a business which is so rapidly expanding that it is, perhaps, not worth their while to take special pains to induce consumers to adopt electrical heating. The gain would all the same be very great to the supply companies, as it would give them a heavy day load. That there is already a considerable demand for electric heating apparatus is evidenced by the catalogue before us, which describes appliances for meeting almost every conceivable want, both for domestic and scientific or laboratory purposes. Some of the latter apparatus would be very convenient in laboratories where electric current is available, as it affords easier means of regulation and is safer than gas, and also allows any desired temperature to be obtained a second time with much less trouble.

WE have received from the publishers, Messrs. Iliffe and Sons, Ltd., the Christmas number of *Photography*, a number which will be welcomed by all interested in the art of picture making. No pains seem to have been spared to make the magazine all that could be desired in the way of quality of paper and printing, while the text is of very general interest and the reproductions of numerous well-known photographs excellent. In the opening article a brief account is given, with illustrations, of three of the foremost photographic artists in France, and we may suggest to those who are not familiar with their style of work that much may be learnt from the article. The second contribution is on a subject which interests every photographer, but the importance of which is not often thought of until too late. One recollects with regret how many good negatives would have been greatly improved if only a figure had been inserted or placed in another position or even omitted altogether. Valuable hints on this score will be found in the chapter entitled "the introduction of figures into landscape pictures," and much can be gathered from the excellent and appropriate illustrations. The main part of this publication is devoted to criticisms and reproductions of many pictures by well-known photographers, which, as is stated, is a reprint in a revised form from *Photography*. The number concludes with a set of sixteen borders with different designs for Christmas cards, all of which are copyrighted, but are placed at the disposal of amateurs and professionals desiring to use them for their own cards.

THE Imperial Department of Agriculture for the West Indies has issued a full report on sugar-cane experiments conducted at Antigua and St. Kitt's in the season 1900–1901. The report is in two parts, the first, of 32 foolscap pages, dealing with experiments with varieties of sugar cane, with an appendix on the chemical selection of sugar cane; and the second, of 78 pages, with manurial experiments. Mr. Francis Watts, chemist-in-charge, states that the variety and manurial experiments involved the analysis of the juice from upwards of 900 plots, while those on chemical selection necessitated the determination of the sucrose in 600 canes. Taking the mean results of the experiments in Antigua, cane D 95 occupies the best place with 8158 lb. of sucrose per acre in juice, Mont Blanc variety following with 7256 lb., while B 147, the best Barbados seedling, stands twelfth on the list with 6050 lb. The means for ratoon canes, however, place B 147 first with 7164 lb. In St. Kitt's, one of the most promising of the Barbados canes, B 208, stands first with 9817 lb., Naga B second with 8956 lb. and B 147 third with 8874, Mont Blanc and D 95 being respectively eleventh and twelfth on the list. On the question of chemical selection the results obtained were not conclusive. Polarising the juice of 200 "high" canes and 200 "low" canes, the difference proved so small that it may lie entirely within the limits of experimental error. The manurial experiments are fully described, with forty-three tables of particulars. They indicate the possibility of growing good crops of plant canes with the use of pen manure only (including such organic manures as green dressing), and when it is obtainable in sufficient quantity artificial manure is unnecessary. If there is no pen manure, fields in good condition will produce good crops

with the aid of artificial manures. What should be done with phosphate is not clear. Artificial manures are unremunerative on land in poor mechanical condition. It is recommended that energy should be devoted to raising pen manure rather than spend money on artificial manures. Experiments are being undertaken to determine whether it will be remunerative to use artificial manures in growing green dressings.

GEOLOGICAL surveys in the United States take a more comprehensive view of geology than is prevalent elsewhere, as they deal generally with natural history. The State Geologist of Alabama has issued a bulky volume on the plant life of the State, by Dr. Charles Mohr. In it are enumerated all the known species of native plants, with their synonymy, localities and mode of occurrence. The author makes some remarks on the spontaneous flora in its relation to agriculture, and observes that the fitness of the land for the production of a special crop can often be ascertained by the farmer from the character of the vegetation alone, without having to resort to costly and time-consuming experimentation.

THE Geological Survey of India has published an account of the Son Valley in the Rewah State and of parts of the adjoining districts of Jabalpur and Mirzapur, by Messrs. R. D. Oldham, P. N. Datta and E. Vredenburg (*Mem. Geol. Surv. India*, vol. xxxi. part i., 1901). The report is accompanied by a colour-printed map on the scale of an inch to four miles, and this shows the exposed areas of unfossiliferous and more or less metamorphosed rocks, a red shale series, and overlying divisions of the Vindhyan and Gondwana groups, which have been regarded as representing Silurian and Jura-Trias respectively. The present work relates almost wholly to the stratigraphical, petrographical and physical questions. There is an almost complete absence of minerals of economic value and apparently also of fossils. Special attention is drawn to the porcellanites of the Lower Vindhyan series, which are regarded as volcanic tuffs.

DR. FRITZ NOETLING describes the fauna of the Miocene beds of Burma ("Palæontologia Indica," new series, vol. i. 1901). Two groups of Tertiary strata are recognised; the lower, characterised by a marine fauna, is considered to be of Miocene age, and the upper, characterised by fluviatile and terrestrial forms of life, is regarded as Pliocene. The Miocene deposits yield remains of Anoplotherium, Crocodilus, Python and Myliobates, which suggest comparison with higher Eocene and Oligocene strata. The author, however, maintains that the beds are newer than the Bartonian (Eocene), and he has "purposely refrained from mentioning the Oligocene," as, in his opinion, "no evidence warrants the adoption of this name for any part of the Indian Tertiary system." The fauna is composed mainly of Lamellibranchs and Gasteropods, and these exhibit relationships with the Eocene of France and with the recent fauna of the western Pacific. Thirty per cent. of the species are direct ancestors of forms living in the Indian Ocean, but this recent fauna contains also a foreign, probably European, element of Miocene origin. One of the author's conclusions is that there was no direct communication between the Miocene Ocean of Europe and India during the Miocene period, as there is not a single species common to the two areas. The vertical range of the species is very restricted.

THE Report of Mr. Edgar Thurston, superintendent of the Goverment Museum, Madras, for the year 1900–1901 has reached us, and contains much interesting information concerning the work done in the various departments of the institution, particularly in the case of those devoted to anthropology, natural history and industrial economics. During the year under review four parts of the *Bulletin* of the Museum were issued, the contents of which have already been referred to in these columns.

THE Baschkirs are an interesting group of peop who live on the eastern slopes of the Urals; formerly they were all nomads, but they have been constrained by the Russian Government to become more or less settled, and they now constitute three groups—the forest- mountain- and steppe-Baschkirs. Hofrat Peter von Stenin gives in *Globus* (Bd. lxxx., Nr. 10, p. 150) an ethnographical illustrated sketch of these people, with references to the literature of the subject, but he omits the brilliant essay on their sociology by M. Edmond Demolins in *La Science Sociale* (tome ii., 1886, p. 405), which is based upon the observations of Le Play in the second volume of his "Ouvriers Européens." The difficulty with which a pastoral people take to agriculture is indicated by both the German and French authors in a manner characteristic of their several nationalities.

THE anthropological investigations in connection with the Madras Government Museum are being conducted with energy and ability, the last research being by Superintendent F. Fawcett on the ethnography of the Nâyars of Malabar. The account is published in the *Bulletin* of the Museum (vol. iii. No. 3) and is illustrated with eleven plates. The Nâyars, the Nareæ of Pliny, were the swordsmen, the military caste of the west coast of India. They are said to be the most complete existing example of inheritance through females. Their average stature is 1·656 m., the cephalic index 73·1, and nasal index 76·8; that is, they belong to the somewhat short, long-headed, distinctly dolichocephalic mesorhine group of the non-Aryans of southern India. The customs relative to marriage, birth, death are carefully narrated. The religion is described, special mention being made of serpent worship and certain festivals, and astrology and magic.

MR. C. J. HERRICK, the well known author of the "Mammals of Minnesota," contributes to the October number of the *Journal of Comparative Neurology* an important paper on the cranial nerves and cutaneous sense-organs of the North American cat-fishes, or siluroids. Starting with Merkel's discovery of the divisibility of the cutaneous sense-organs into two chief types—the "terminal buds" and "neuromasts," or organs of the lateral-line system—the author has endeavoured to ascertain whether these two types are supplied by different nerves, as has been thought probable by other investigators. The investigation has involved the complete working-out of the nervous system of the common American cat-fish, *Ameiurus catus*.

THE latest issue (vol. xxix. part iii.) of Gegenbaur's *Morphologisches Jahrbuch* contains five papers, all dealing with the morphology and development of the lower vertebrates. Prof. B. Haller discusses the primitive kidneys of the spiny dog-fish, Mr. H. L. Bruner the respiratory mechanism of amphibians, as exemplified by the myology of two genera, and Mr. J. F. Holm the finer anatomy of the nervous system of the lampreys of the genus Myxine. The first appearance of the olfactory organ in the larva of the true lampreys forms the subject of an article by Dr. W. Lubosch, while F. Hochstetter describes certain variations in the aortic arch and the bases of the arteries springing from the same in reptiles.

THE August issue (vol. iv. part i.) of *Annotationes Zoologicae Japonenses* contains five papers, for the most part on somewhat abstruse biological subjects, and thus bears witness to the thoroughness with which natural science is studied in Japan. In the first communication Prof. Mitsukuri discusses "negative phototaxis" in the Japanese periwinkles and its influence on their habitat. Knowing that these molluscs like shallow water, it is argued that when the depth becomes too great for their comfort they endeavour to escape by crawling in the direction which appears to them the darkest—that is towards the land. In a second paper Mr. S. Hatta reviews the lampreys of Japan;

while in a third Dr. Bashford Dean adduces evidence to prove the existence of vestiges of an original holoblastic cleavage in the egg of the Japanese representative of the Port Jackson shark. This discovery is of the highest morphological importance, sharks' eggs having been hitherto regarded as typically meroblastic. "No one, I fancy," writes the author, "would have been bold enough to have prophesied that the wide difference between the typically meroblastic egg of the shark and the holoblastic egg of such a teleostome as a sturgeon might come to be bridged over within the limits, not of fossil sharks, but of recent sharks themselves."

THE singular bulbiform seeds of certain Amaryllideæ—especially species of Amaryllis and Crinum—are the subject of an interesting paper by Dr. A. B. Rendle in the November number of the *Journal of Botany*. These seeds are of three kinds:—(1) True seeds developed from a normal ovule, the outer integument of which becomes thick and fleshy after fertilisation, and forms the substance of the bulbiform mass; (2) true seeds developed from a naked ovule, the fleshy substance being derived entirely from the endosperm, which develops chlorophyll in its outer layers and continues to grow for some time; (3) a vegetative growth replacing the seed; a normal ovule is produced, but a viviparous growth of an adventitious shoot and root takes place at the base, and a bulbil is formed, the ovule integuments forming the outer coats.

DR. FRIEDRICH BERWERTH has communicated to the Vienna Academy of Sciences a paper on soundings from the eastern Mediterranean. In regard to the distribution of calcareous mud, it is found that two principal zones exist, one to the north of the Nile delta, which extends along the Syrian coast and contains but little carbonate of lime (5 to 15 per cent.), while the other, consisting of the remainder of the eastern Mediterranean, is largely calcareous, the proportion of chalky matter being on an average 60 per cent., with variations of 20 per cent. above and below this average. The relation between the proportion of calcareous matter and the depth appears to be at variance with what would be expected from Murray's theory. The sedimentary matter consists, in general, of (1) calcareous organic remains (mollusca and foraminifera), (2) fragments of siliceous matter of organic origin, including sponges and radiolaria, (3) fragments of minerals and rocks, (4) a precipitate, partly calcareous, partly argillaceous, showing little microscopic structure, which constitutes the main part of the mud.

A SOUND and practical knowledge of "The Cyanide Process of Gold Extraction" can be obtained from the volume on that subject by Prof. James Park, published by Messrs. Charles Griffin and Co. The first English edition was favourably noticed in these columns last year (vol. lxii. p. 148), and the second has now appeared. The whole volume has undergone revision, and the new matter includes a detailed description of well-designed slime and sulphide plants now in use in the great mining centres of the world.—Another of Messrs. Griffin's technical handbooks which has reached a second edition is "Practical Coal Mining," by Mr. George L. Kerr, the first edition of which was reviewed in NATURE of February 28 (vol. lxiii. p. 417).

LOW-TEMPERATURE research at the Royal Institution during the past seven years has been assisted by the Hodgkins Trust Fund—a sum of 100,000 dollars left by the late Mr. T. G. Hodgkins as a source of income to be employed in the "investigation of the relations and co-relations existing between man and his Creator." To show what has been done towards this end, Miss Agnes M. Clerke has prepared for the Hodgkins Fund a popular essay on Prof. Dewar's work at the Institution from 1893 to 1900. The essay traces the course of his researches in the physics and chemistry of low temperature, and contains, in addition, three illustrations showing the lecture table of the Royal Institution upon the occasion of the centenary commemoration lecture on liquid hydrogen, and the elaborate refrigerating machinery and liquid hydrogen apparatus used by Prof. Dewar.

THE current number of the *Berichte* contains a paper, by A. Hantzsch and A. Holl, on sulphimide. This substance was first obtained by W. Traube from the products of the action of ammonia upon sulphuryl chloride, and the formula SO_2NH was attributed to it, from the analyses of its salts. In the present paper the authors have been successful in obtaining sulphimide in the solid form, and have found by molecular weight determinations that it resembles cyanuric acid in being trimolecular $(SO_2NH)_3$. They have also succeeded in isolating the methyl ester of this substance, and have found that this is also trimolecular. It is pointed out that the analogy between the nitrogen derivatives of carbonic acid and sulphuric acid is much closer than has hitherto been supposed.

Bulletin No. 186 of the U.S. Geological Survey contains an interesting study of pyrites and marcasite, by Dr. H. N. Stokes, and describes a method for the quantitative determination of these minerals when in mixture. The method depends upon the fact that when either mineral is boiled with an excess of a solution of ferric salt to complete reduction of the latter the ratio of sulphur oxidised to mineral decomposed is perfectly definite and characteristic of each mineral, provided certain standard and easily controllable conditions are observed. Under these conditions the percentage of sulphur oxidised on pyrites is about 60·4 per cent. and on marcasite about 18 per cent. of the total sulphur. The application of this method has thrown considerable light on several doubtful questions relating to the dimorphous FeS_2. It is shown, for example, that density is not a trustworthy means of determining one mineral in presence of the other, that the hypothesis that most natural specimens are mixtures of the two is without foundation, and that there is no evidence of a difference of valency of iron in the two minerals. Specimens crystallising in the regular system are true pyrites, whilst those forming rhombic crystals are true marcasite.

THE additions to the Zoological Society's Gardens during the past week include a White-crowned Mangabey (*Cercocebus aethiops*) from West Africa, presented by Mr. Fred Gordon; a Cape Zorilla (*Ictonyx zorilla*), a Derbian Zonure (*Zonurus giganteus*) from South Africa, presented by Mr. W. L. Sclater; a Gazelle (*Gazella dorcas*) from Egypt, presented by Mrs. Bensusan; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. John Booth; a Bauer's Parrakeet (*Platycercus zonarius*) from South Australia, presented by Miss Gillam; a Lobed Chameleon (*Chamaeleon parvilobus*) from South Africa, presented by the Rev. Duncan Travers; a Chacma Baboon (*Cynocephalus porcarius*) from South Africa, an Alligator Terrapin (*Chelydra serpentina*), a Pennsylvanian Mud Terrapin (*Cinosternum pennsylvanicum*), a Muhlenberg's Terrapin (*Clemmys muhlenbergi*), six Long-eared Sun Fish (*Leptomis auritus*) from North America, deposited; three Australian Wild Ducks (*Anas superciliosa*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE LEONID METEORS.—Arrangements are being made at several observatories to record, by eye observations and photography, any Leonid meteors which appear during the epoch of the Leonid meteoric shower, November 14–15.

NEBULOSITY SURROUNDING NOVA PERSEI.—A telegram from the Centralstelle at Kiel announces that from the examination of photographs taken with the Crossley reflector of the Lick

Observatory, Prof. Perrine has found four principal condensations of the faint nebula surrounding Nova Persei, and that these have been displaced *one minute of arc* to the south-east in a period of six weeks.

MEAN PARALLAX OF STARS.—No. 8 of the *Publications* of the Astronomical Laboratory at Groningen contains an investigation, by Prof. J. C. Kapteyn, of the mean parallax of stars considered with reference to their determined proper motions, magnitude and spectral type.

PLANETARY INFLUENCE ON SUN-SPOT PERIOD.—In the Paris *Comptes rendus* (vol. cxxxiii. pp. 726–729), Prof. Birkeland gives the discussion of a further attempt to trace any possible connection between the 11-yearly sun-spot period and the gravitational disturbance of the planets Mercury, Venus and Jupiter, using observations made from 1892–1896. He comes to the same conclusion as formerly, that the variations cannot be traced to planetary influence.

DISTRIBUTION OF COSMIC VELOCITIES.—Profs. J. C. Kapteyn and W. Kapteyn have recently completed the elaborate treatment of two preliminary communications made by the former to the Academy of Sciences at Amsterdam, and the first part of the treatise is published as No. 5 of the *Publications of the Astronomical Laboratory of Groningen*.

In this an attempt is made to deduce, from the available observations of proper motion, the law defining the relation between the number of stars having linear velocities of determined values, or shorter, the law by which the frequency of a linear velocity is given as a function of its magnitude. The main assumption on which the derivation is based is "the real motions of the stars are equally frequent in all directions."

In the papers mentioned above it had been stated that certain inequalities existed in the distribution of velocities with respect to the apex of the solar motion, and that these had been traced to the influence of a systematic error of the proper motions in declination. It is now thought that many of the former difficulties will be removed by the introduction of a correction for this anomaly.

The formulæ given are developed to such terms as are likely to provide for any great future extension of the accuracy attainable in proper motion determinations, and although the time may come when spectroscopic investigations of velocity (the accuracy of which does not depend on the distances) will supersede the present observations, at present the possibility of having two independent determinations from different components of the real motion is a valuable and important consideration.

The second part of the work, dealing with the application of these formulæ to the observations, will be presented in a later publication.

THE INFLUENCE OF THE MEDITERRANEAN PEOPLES IN PREHISTORIC BRITAIN.[1]

THE progress of archæological discovery during the last twenty years has thrown a flood of light on the relation of the prehistoric period in Europe north of the Alps to the civilisation of the Mediterranean in the period embraced by history. We are now in a position to recognise the source from which the inhabitants of middle and northern Europe, and of the British Isles, obtained the art manifested in their articles of daily use, and we are able to trace them back to that wonderful Mediterranean civilisation, proved by the labours of Schliemann to be older than the Greeks and shown recently by Mr. Arthur Evans to have occupied a commanding position in the island of Crete. Schliemann discovered its range over the eastern Mediterranean from Troy to the Peloponnese, Evans extends it to almost within sight of Italy, where the Etruscan civilisation is the dominant factor at the dawn of history.

The picture presented to us of the Mediterranean region during the period extending from the establishment of the Greeks in the east and the Romans in the west, backwards to at least 2300 years B.C., as proved by the discoveries at Knôssos, may be outlined as follows. A civilisation of the very highest order existed in the region extending from Italy eastwards through the Ægean Sea to Asia Minor, equal in splendour to that of Egypt and Assyria. Although it borrowed many things from both, it was a development independent of both, and, so far as the evidence goes, it appears to have been indigenous in the Mediterranean region and Asia Minor. Whether or no it is as ancient as that of Egypt and Assyria is an open question.[1] It was common to the ancient Trojans and Mycenæans overthrown by the Greeks, to the Cretans, and to the Etruscans overthrown by the Romans. It is worthy of remark that in the eastern Mediterranean it formed the foundation of Greek art, while it survived in the west under the name of Roman, its possessors in each case being absorbed into the Greek and Roman peoples.

The establishment of the Phœnicians in the Eastern Mediterranean, at least as far back as the seventeenth century B.C., as proved in the records of Egypt, has also to be considered. They were the great merchants and carriers, distributing the wares of Egypt, and later of Assyria, to the various Mediterranean peoples, founding colonies here and there, among the greatest of which was Gades (Cadiz), about 1100 B.C., and Carthage, 814 B.C. Their fleets in penetrating westward had to contend with the Etruscan maritime power, dominant in the western Mediterranean. They and the Etruscans were the great distributors of metal, more particularly bronze, and their ships penetrated in later times far northwards along the Atlantic shore. It is not at all improbable that Phœnician ships coasted along the Atlantic as far north as the British Isles, bringing with them the wares of the Mediterranean and returning with tin from Cornwall and gold from Ireland. There is, however, no absolute proof of their presence in Britain, because, like the English of to-day, they had no art of their own and merely imitated the art of other peoples.

During the period under consideration, the various peoples inhabiting the Mediterranean were sufficiently organised to allow of a confederacy for the attack of Egypt. The first mention of a European people in the Egyptian annals is the attack of the Sardones and the Tyrrhenes (Etruscans) and their defeat by Ramses II. in the seventeenth century B.C. This was followed about seventy years afterwards by a more formidable combination, in which the two above-mentioned peoples were joined by the Sicels, Lycians, Achæans and Lybians. The allies advanced by sea and land, conquered part of the Delta, and were defeated after a desperate struggle by Meneptah I.

It remains now to trace the influence of the Mediterranean civilisation through middle and northern Europe. The two oldest routes of traffic are those starting from the head of the Adriatic, from the ancient Etruscan city of Hatria. The first runs by Trieste, Laibach, Gratz and Bruck, to Presburg, and thence past Breslau and along the Lower Vistula to the amber coast of Samland. The second, or western route, takes the line of the Adige, past Verona and Trient, over the Brenner Pass into the valley of the Inn, crossing the Danube either at Linz or Passau. Thence it ran through the Bohemian passes into the valley of the Elbe, and made for the amber coast of Schleswig and Holstein. These were the two principal routes taken by the caravans, which brought to the inhabitants of middle and northern Europe in the Bronze Age bronze swords, axes, daggers, bracelets, brooches and other articles from the south, carrying back, among other things, the amber so highly valued by the Mediterranean peoples. There were probably similar routes to these northwards and westwards over the plains of France, starting from the Alpine passes, and along the river valleys, along the lines afterwards followed by the Greeks of Marseilles (Massilia). It was probably by one or other of these routes that brooches, swords and other implements of southern derivation, arrived at the sea-board of the North Sea and Atlantic, and were brought by ship into Britain and Ireland. Ireland, it must be noted, at this time was the *El Dorado* of the west, attracting adventurers from the south both by sea and land.

These routes were also used in the prehistoric Iron Age north of the Alps, and along them metal work of most beautiful design, brooches and bracelets, mirrors and other articles, belonging to the so-called "late Celtic" art, were introduced into Britain—such, for example, as the mirror, brooch, and bronze bowl found at Glastonbury. In Ireland this art is amply represented in the numerous golden and bronze ornaments.

The Greeks, too, after their establishment at Massilia in the sixth century B.C., took up this trade, making clearly defined routes through France, to the Atlantic shore and to the Rhine valley, along which the tin of Cornwall was carried overland to

[1] Presidential Address by Prof. Boyd Dawkins, D.Sc., F.R.S., to the Vesey Club, on October 15, illustrated with slides.

[1] I feel unable to accept Prof. Flinders Petrie's conclusion, that some of the pottery found in the tombs of the first dynasty in Egypt belongs to the Mycenæan or Ægean pottery, and therefore goes back as far as 4750 B.C.

the south. They also probably carried on a trade by sea. In 325 B.C., Pythias, the first explorer of Britain known to fame, was sent at the head of an expedition from Massilia, working his way along the Atlantic coast and wintering somewhere near Dover. From this point he sailed to the Orkneys and Scandinavia, returning by way of the amber coast at the mouth of the Elbe. The Greek influence was also felt from the northern borders of Greece through Germany. In Britain a coinage which was copied from the Stater of Philip of Macedon marks the close of the prehistoric Iron Age, when the Greek influence was dominant. In Ireland, it is worthy of note, none of these coins have been met with, and it is likely, therefore, that the Greek influence was never felt in that island.

From this outline it is clear that the principal artistic development in Britain, in the Bronze and prehistoric Iron Ages, was due to the art of the south, and that it was derived mainly from the Mediterranean civilisation, including under that term Mycenæan, Ægean, Etruscan and Dalmatian art, and that in later times it was aided by intercourse with the Greeks.

W. BOYD DAWKINS.

THE MOVEMENTS OF PLANTS.[1]

IT is sometimes asserted that the power of movement is a character distinguishing animals from plants. This statement arises to some extent from an obvious confusion of thought. Trees are stationary, they are rooted to one spot; but they are not, therefore, motionless. We think them so because our eyes are dull—a fault curable with the help of a microscope. And when we get into the land of magnification, where the little looks big and the slow looks quick, we see such evidence of movement that we wonder we do not hear as well as see the stream of life that flows before our eyes.

In speaking of the cells of which plants are built, Mr. Huxley said that a plant is "an animal enclosed in a wooden box, and Nature, like Sycorax, holds thousands of delicate Ariels imprisoned in every oak." It is this delicate prisoner, the living protoplasm, that we may watch pacing round its prison walls. And we may see it stop as though frightened at our rough usage, and then, after a hesitating twitch or two, we see it recover and once more flow round the cell. Or we can see under the microscope minute free-swimming plants rushing across the field of view, all one way, like a flock of little green sheep that we can drive to and fro with a ray of light for a sheep dog.

But I am not going to speak to-night of microscopic matters, but rather of things on a bigger scale which can be seen with the naked eye. I will begin by trying to show that very obvious movements are to be seen in every kitchen garden or in every garret window where a scarlet runner is grown for its red flowers' sake.

If you will examine a scarlet runner, you see that the shoot is not completely vertical, but bends over to one side. To record the movements of the plant a series of photographs may be taken vertically from above the plant, so that the end of the shoot shows like the hand of a watch against a sort of clock-face on which the points of the compass are marked. These photographs will show how the shoot swings round in its instinctive search for another stick to climb up.

This well-known movement is performed by a co-ordinated series of curvatures the exact nature of which need not trouble us now. Let us rather consider the less obvious power of coordination which enables a plant to grow upwards in a straight line. Think of a forest of pine trees, hundreds of thousands of them, all growing vertically up towards the sky. Here is a clear case of movement, for the leading shoots were once but a few inches from the ground, and now they are crawling along vertical lines 100 feet up in the air. It may be said that this is mere increase in size, not movement in the ordinary sense. But I can show you that the trees could not grow in this way had they not a power of curvature to which the name of movement cannot be refused.

As it is not easy to experiment on pine trees, we will use a pot of mustard seedlings, which represents in miniature a forest of vertical stems. Now suppose the flower-pot upset and left lying on its side for a few hours: the seedlings will be found to have all recovered the vertical position, and they have done so by a bend which is just as much a case of movement as the flexure of a man's arm, though it is effected by a very different mechanism. Not everyone realises how rapid this movement is. Fig. 1 is from a diagram made in the ordinary course of class-work at Cambridge, and illustrates this point. A shoot of *Valerian* was placed horizontally at 2.17 and a black line painted like a silhouette on a vertical sheet of glass to record its position at 2.30; similar lines were painted at intervals, forming a record of fairly rapid movement. If greater delicacy of observation had been practised, it would have been easy to show that the plant begins to curve up within a few minutes of being placed horizontally.

It is a remarkable fact that the plant should be stimulated, or stirred up, to a definite curvature by merely placing it horizontally. The curvature tends to bring the plant into the upright position, and when the whole stem has reached the vertical, the stimulus ceases to exist. It is as though the plant were in a condition of content when vertical and of discontent in any other position, and as though the discontent expressed itself in curvature.

But the plant does not gain the vertical by a single continuous curvature; at first it overdoes the thing (see Fig. 1) and the end of the shoot may pass beyond the vertical by 20°–30°. But this new position, inasmuch as it is not vertical, originates a new stimulus, and the new curvature which follows brings the shoot back towards the upright position. It may again overshoot the mark, but by repeated corrections it finally attains the normal upright posture.

It is this power of correcting the line of growth whenever it deviates from the upright that enables the pine tree to grow

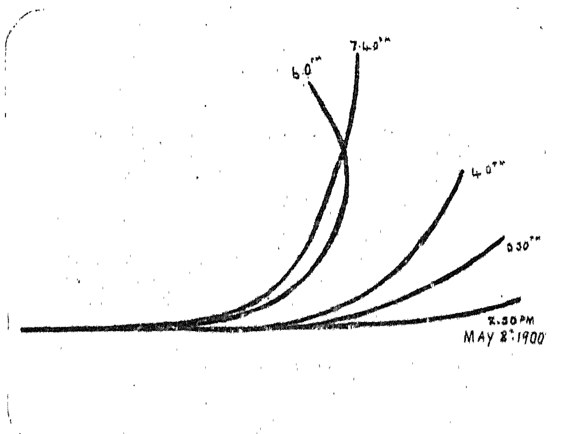

FIG. 1.—A *Valerian* stem curving geotropically.

straight upwards. And this is what I meant when I said that its habit of growth depends on regulated curvature to which no one can refuse the name of movement.

The pine and the seedling have, in fact, a wonderful kind of sensitiveness—a sensitiveness to the force of gravity. To those accustomed to think of Mimosa as the sensitive plant *par excellence* my words may sound strange. But the sensitiveness of Mimosa is crude by comparison with that of the seedling. A plant with a perception of the position of the centre of the earth and a power of growing along the line so perceived is a much greater miracle than a leaf that closes its leaflets when burnt or cut or shaken.

I hope I shall be able to prove to you that we can point to certain parts of the plant which have the special quality of the perception of gravitation, but we are at present ignorant of how the act of perception is effected. We know something of the machinery of hearing or vision in animals, but in plants we can only guess that when a cell is placed horizontally a resulting change of pressure on the protoplasm produces that loss of equilibrium which is translated into curvature.[1]

The use of this gravitational sensitiveness is clear enough. It is to the pine tree what a plumb-line is to the builder, for

[1] Evening lecture delivered at the Glasgow meeting of the British Association, September 16, by Francis Darwin, F.R.S.

[1] It is, however, probable that Nemec and Haberlandt are right, and that the stimulus depends on the pressure of solid particles, *e.g.* starch-grains, on the protoplasm. See their papers in the *Deutsch Bot. Ges.*, 1900.

neither plant nor man can build high unless he builds straight. A man has a general perception of the verticalness of his body and of surrounding objects, but he does not trust to this sense in placing brick on brick to make a house. He uses a plumb-line which tells him through his eye the precise line along which he must pile his bricks. The tree has also to pile one over another the cells or chambers in which its protoplasmic body lives, and this too must be done along a vertical line; but the plant does it by the sensitiveness to gravity of which I have spoken.

It must be clearly understood that gravity does not act directly on the growth of plants. It does not act as a magnet acts on iron, or to take a better example, it does not simply act as gravity acts on the plumb-line in which the string is kept in a vertical straight line by the weight. It might be supposed that in some occult way the stem was mechanically kept straight like the string, and this indeed was the view formerly held about such roots as grow straight down into the earth. But it is not so; the thing is not explicable mechanically. Gravitation is nothing more than a sign-post or signal to the plant—a signal which the plant interprets in the way best suited to its success in the struggle for life, just as what we see or hear gives us signals of the changes in the exterior world by which we regulate our conduct.

You will say that this is hard to prove, and indeed, like other biological hypotheses, it can only be shown to be true by explaining a number of facts. It is interesting to try to explain the facts without the assumption in question. If gravity does *not* act indirectly as a signal it must act directly, and we must find a reason why, in the case of the mustard seedling above referred to, the stem has grown up and the root down. There is absolutely nothing in their structure or manner of growth to help us to see why this difference of behaviour under identical conditions should exist. And if, instead of placing the mustard seedling in the dark we had grown it near the window, we should have come across another remarkable phenomenon, namely, that the stem grows towards, the root away from, the light—and this is equally inexplicable on a mechanical basis.

But it may be said that it is not fair to compare a root and a stem which are structurally unlike. Let us, therefore, stick to roots. When the root of a bean has grown vertically down into the soil for some distance it begins to bud forth into side roots. These are exactly like the primary root from which they spring; there is no difference in structure or in machinery of growth. Yet the secondary roots do not grow vertically down, but obliquely, or in some cases horizontally. There is one more striking fact about the roots of the bean. The secondary, like the primary roots, give off branches, and these—the tertiaries—behave differently from both primary and secondary roots. For instead of directing themselves vertically or horizontally, they simply treat the force of gravity with contempt and grow just where fancy leads them. The point on which I wish to insist is that it is impossible to explain on any theory of the direct action of gravity why the three orders of roots have three distinct modes of growth. They may remind us of three generations, grandfather, father, and son, all of one blood and yet behaving towards the universe in three distinct ways—a fact not unknown in human society.

On the other hand, it would not be difficult to show that the behaviour of the three orders of roots is well suited to the plant's needs, and therefore we can understand how the power of behaving in three different ways to the same signal has been evolved. The main root takes the shortest course to the deeper layers of earth; the four or five ranks of secondary roots divide the world between them and push forth all round, keeping slightly below the horizontal; the tertiaries take it for granted that their predecessors have done the usual thing and that they can satisfactorily occupy the spaces left among their elders by random growth. The fact that the tertiary roots have no specialised sensitiveness of gravitation shows that their unregulated growth is good enough for the necessities of the case. For among organised beings necessity is the mother of development, and what their brethren of second rank have developed they too could assuredly have gained. To this point of view I shall return, but first I should like to give a few more instances of actions carried out in response to the signal of gravity; and these examples shall be from stem-structures.

The flower-heads of a clover (*T. subterraneum*) bury themselves in the ground, thus effectually sowing their own seeds, and they are guided to the ground by their unusual capacity of curving down and directing themselves like a primary root towards the centre of the earth.

Other flower-stalks are guided by gravitation for quite different purposes. Take, for instance, a common narcissus. In the young condition there is a straight shaft piercing the ground

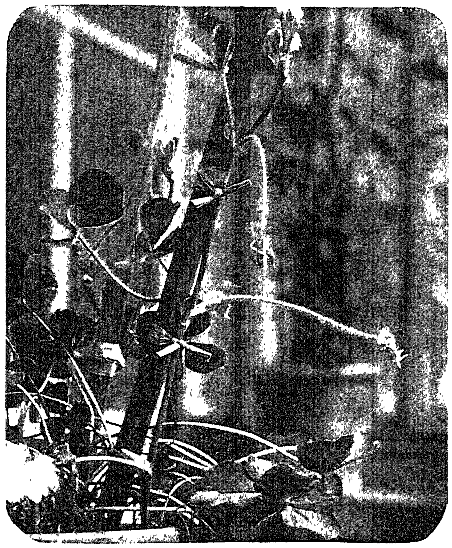

FIG. 2.—*Trifolium subterraneum*. Two flower-heads in the fruiting condition: the upper one has bent sharply and is growing vertically downwards.

with its compact pointed flower bud; but as the flower opens the stalk bends close to the top and brings the flower-tube into a roughly horizontal position, where it shows off its brightly coloured crown to the insects that visit it. The flowers are guided to the right position by the gravitation sense, and they increase or diminish the angular bend in their stalk till the right position is attained, as shown in Fig. 3. The same thing

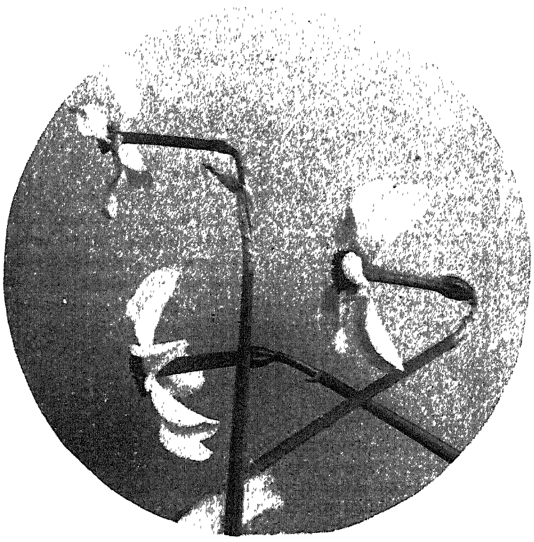

FIG. 3.—Narcissus flowers.

may be easily seen in the larkspur. So long as the plant is left to itself the flower-stalk remains quiescent, but if the stem is displaced so that the flower makes the wrong angle with the vertical, the stalk is stimulated to curve, and bends until the flower is once more in its proper position.

All these cases of plants executing certain useful curvatures

which occur when the plant is displaced as regards the vertical and cease when the habitual relation is reached, all these, I say, seem to me only explicable on the theory that gravitation does not act as a mechanical influence, but as a signal which the plant may neglect entirely, or, if it notices, may interpret in any way; that is, it may grow along the indicated line in either direction or across it at any angle. You may say that this is no explanation at all, that it only amounts to saying that the plant can do as it chooses. I have no objection to this, if you will first define the meaning of the word "choice."

I AM now going to deal with the subject of movement from a somewhat different point of view, namely, to show that it is possible to discover the part of the plant which reads the signal, and this is not necessarily the part that executes the correlated movement. In the reflex movement of an animal (for instance, a cough produced by a crumb going the wrong way), we distinguish the irritation of the throat and the violent action of the muscles of the chest and abdomen, and further, the nervous machinery by which the stimulus is reflected or switched on, by way of the central nervous system, from throat to coughing muscles. In the plant, too, if we are to compare its movements to the reflexes of animals (as has been done by Czapek), we must distinguish a region of percipience, another of motility, and the transmission of an influence from the percipient to the motor region.

Transmission of a stimulus has long been known in Mimosa, but in the far more important curvatures which we are now considering it was not known to exist before the publication of the "Power of Movement in Plants." There is an experiment of Rothert's[1] which we do in class work at Cambridge, and which only differs from my father's classical experiment in the fact that a much more perfectly adapted plant is employed. The plant in question is a grass, *Setaria*, which has a remarkable form of seedling. When the grain germinates it does not send up a simple cylindrical sprout like an oat, but a delicate stem terminating in a pointed swollen part which looks like a little spear-head. When a group of *Setarias* is illuminated from one side, they bend strongly over, with their little spear-heads all pointing straight at the light. The spear-heads do not bend; the whole movement is carried out by the stalk on which the head is supported. But the remarkable thing is that it is the spear-head and not the stalk which perceives the light. This is easily proved by covering the heads of a few *Setarias* with opaque caps. For the result is that the blindfolded seedlings remain vertical while their companions are pointing to the light. Thus the part which bends is unaffected by illumination, and the part which is affected does not bend. The spear-head is the percipient organ, the shaft or stalk is the motor region, and from head to shaft an influence has clearly been transmitted.

My father and I made an attempt to prove the same thing for the gravitation-sense of roots, that is, to prove that the tip of the root is the region in which the force of gravity is perceived by the plant. Our method of proof does not hold good, but our conclusions are true after all. When gravitation is the stimulus, the experiment is much more difficult than when light is in question, because now that fairy godmothers are extinct we must not hope for a substance opaque to gravitation, a substance with which we might shelter the root-tips from the force of gravity as the tips of the *Setaria* seedlings were sheltered from light.

The plan adopted by us was simply to cut off the extreme tip of the roots, and fortunately (or unfortunately) the result was just what was expected—the tipless roots had lost the sense of gravitation and were unable to curve downwards towards the centre of the earth. It was surely natural to believe that the tipless roots failed to bend because their sense-organs—their percipient parts—had been removed. As a matter of fact they had been removed, but it was fairly objected that the operation of removing the delicate tissues at the tip of the root is a severe one, and that the roots which refused to grow downwards were suffering from shock and not from the absence of their sense-organs.

The subsequent history of the inquiry is an instance of the unwisdom of prophesying unless you know. In 1894 an able summary of the question was published in a German journal, in which the impossibility of solving the problem of the gravitational sensitiveness of the root-tip was dwelt on, and immediately afterwards Section K of this Association had the satisfaction of hearing Pfeffer read a brilliant paper giving the long-hoped-for proof that the tip of the root is a sense-organ for gravitation.[1]

Like many other experiments, it depends on a deception or trick played on the plant. The root is forced to grow into a glass tube closed at one end and sharply bent in the middle, resembling, in fact, a little glass boot. The extreme tip is thus kept at right angles to the main body of the root; if the theory we are testing is the right one, a root with its motor region horizontal and its tip vertical ought to continue to grow horizontally, because the tip being vertical is not stimulated by gravity; it is in a quiescent, or, as it were, a satisfied condition, and no bending influence is being sent to the motor region. And this is what Pfeffer and Czapek found. Fig. 4 A, if turned through a right angle, will represent such a root. On the other hand, if the main body of the root points vertically down while the sensitive tip is horizontal, a curvature results, because as long as the tip is horizontal it is stimulated, and the stimulus is transmitted to the motor region. Fig. 4 A shows the tip horizontal; B shows the curvature which brings the tip into the vertical once more.

This experiment proves not only that the tip of the root is the sense-organ for gravity, but also that the motile part is not directly sensitive; in other words, that gravitation is perceived exclusively in the tip of the root. Since the publication of Pfeffer's and Czapek's papers I have been lucky enough to hit on another way of testing the theory that the tip is the percipient organ for gravitation,[2] and I am not without hopes that botanists may become in this question as fertile as Cyrano with his seven ways of flying to the moon.

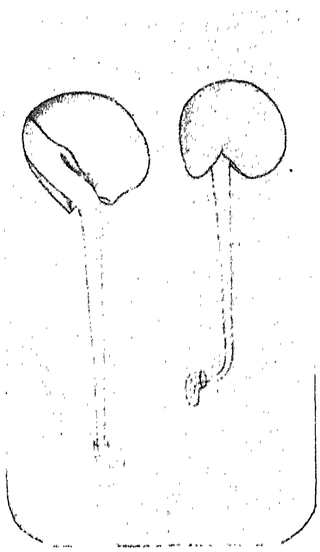

FIG. 4.—Roots in glass boots (from *Pringsheim's Jahrbücher*).

There is a certain kind of inverted action familiarly known as the tail wagging the dog, and it is on this principle of inversion that my experiment is designed. Inversion may in some cases be practised without altering the final result. For instance, it does not much matter whether the thread goes to the needle (the rational masculine plan) or *vice versâ*, as in the orthodox feminine way of threading a needle. In other cases you create what is practically a new machine by inversion, as in a certain apparatus in which the hand of a clock stops still while the clock itself rotates. The effect is still more striking with my plants, for the inversion practised on them entirely changes the character of their movement.

The result may be shown with the seedling *Setarias* of

[1] Cohn's *Beiträge*, 1894.

[1] Pfeffer, in the *Annals of Botany*, September 1894. Further details in Czapek's paper in *Pringsheim's Jahrb.*, 1895.

which I have spoken, or with *Sorghum*, as in Fig. 5. If one of these is supported by its seed with its stem projecting freely in the horizontal plane, the gravitation stimulus makes it bend upwards until the tip is vertical, when the stimulus ceases to act and the curvature comes to an end. If the conditions are reversed, if the seedling is supported in a horizontal position *by its tip*, while the seed projects freely, the result is at first the same, though finally it comes to be strikingly

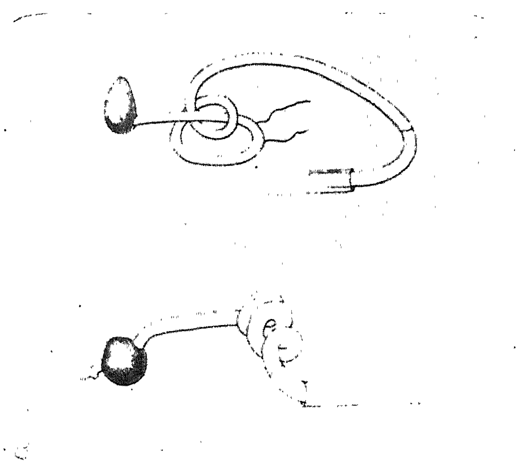

FIG. 5.—Seedling *Sorghums* supported by their tips in horizontal glass tubes. (From the *Annals of Botany*.)

different. The basal end of the seedling is carried upwards by the curvature of the stem; but according to the theory we are testing, the tip of the seedling is the only part of the plant which feels the gravitational stimulus, and the tip of the seedling remains horizontal in spite of the curvature of the stem. Therefore the tip of the seedling is not freed from stimulation as it was in the first case, where the curvature brought the tip into

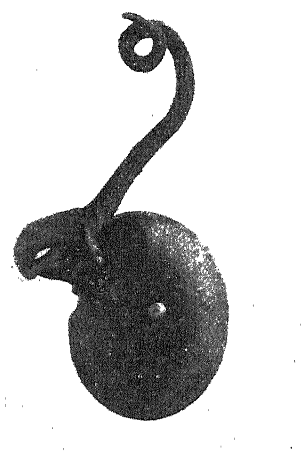

FIG. 6.—A bean-root which had been supported by the tip; the curvature thus corresponds to that in Fig. 5.

the vertical position. The horizontal tip therefore continues to send commands to the stem to go on curving, in a way I can best explain if I am allowed to make the plant express its sensations in words. The tip says to the stem, "I am horizontal, therefore you must bend upwards"; and when this order has been obeyed the tip says, "It is of no use, I am still horizontal—go on bending." The result is that the stem curls up into a spiral like a corkscrew or a French horn, as shown in Fig. 5. I have also been able to get the same result with the roots of beans and peas, as shown in Fig 6.[1]

These unfortunate plants are in the position of a convict on the treadmill; their movements are, from their own point of view, absolutely ineffectual and meaningless. The results are, however, of some importance from our point of view, since they give clear support to the theory which I have now attempted to place before you, namely, that the percipient region is at the tip of the *Setaria* seedling or of the bean root (as the case may be), and that by what corresponds to a reflex action the stimulus perceived by the tip is transmitted to the motor region. I think I may quote my father's words and say that it is hardly an exaggeration to say that the tip acts like the brain of one of the lower animals.

I should like to add a few words on the question how far the movement of plants can be placed under the general laws deducible for the movements of animals. Unfortunately, as soon as we attack this question we are liable to enter regions where for the ignorant there are many pitfalls. We are, in fact, face to face with the question whether in plants there is anything in which we may recognise the faint beginnings of consciousness, whether plants have the rudiments of desire or of memory, or other qualities generally described as mental.

If we take the wide view of memory which has been set forth by Mr. S. Butler[2] and by Prof. Hering, we shall be forced to believe that plants, like all other living things, have a kind of memory. For these writers make memory cover the whole phenomena of life. Inheritance with them is a form of memory, or memory a kind of inheritance. A plant or an animal grows into the form inherited from its ancestors by passing through a series of changes, each change being linked to the preceding stage as the notes of a tune are linked together in the nervous system of one who plays the piano. Or we may compare the development of an animal or plant to the firing of a train of gunpowder, which completes itself by a series of explosions each leading to a new one. To use the language I have been employing, each stage in development acts as a signal to the next.

In the same way the characteristic element in what is done by memory or by that "unconscious memory"[3] known as habit is the association of a chain of thoughts or actions each calling forth the next.

What I wish to insist on is that the process I have called action by signal is of the same type as action by association, and therefore allied to habit and memory. The plants alive to-day are the successful ones who have inherited from successful ancestors the power of curving in certain ways when, by accidental deviations from their normal attitude, some change of pressure is produced in their protoplasm. With the pianist the playing of A has become tied to, entangled or associated with the playing of B, so that the playing of A has grown to be a signal to the muscles to play B: similarly in the plant the act of bending has become tied to, entangled or associated with, that change in the protoplasm due to the altered position. There is no mechanical necessity that B should follow A in the tune; the sequence is owing to the path built by habit in the man's brain. And this is equally true of the plant, in which a hereditary habit has been built up in a brain-like root-tip.

The capacities of plants of which I have spoken have been compared to instincts, and if I prefer to call them reflexes it is because instinct is generally applied to actions with something of an undoubted mental basis. I do not necessarily wish it to be inferred that there can be nothing in plants which may possibly be construed as the germ of consciousness—nothing psychic, to use a convenient term; but it is clearly our duty to explain the facts, if possible, without assuming a psychological resemblance between plants and human beings, lest we go astray into anthropomorphism or sentimentality, and sin against the law of parsimony, which forbids us to assume the action of higher causes when lower will suffice.

The problem is clearly one for treatment by evolutionary method—for instance, by applying the principle of continuity.[4] Man is developed from an ovum, and since man has consciousness it is allowable to suppose that the speck of protoplasm from which he develops has a quality which can grow into consciousness, and by analogy that other protoplasmic bodies, for instance those found in plants, have at least the ghosts of similar

[1] F. Darwin, in *Proc.* Cambridge Phil. Soc., xi.
[2] "Life and Habit," 1878.
[3] Mr. S. Butler's term.
[4] See James Ward, "Naturalism and Agnosticism," i. 283.

qualities. But the principle of continuity may be used the other way up—it may be argued that if a lump of protoplasm can perform the essential functions of a living thing to all appearances without consciousness, the supposed value of consciousness in Man is an illusion. This is the doctrine of animal automatism so brilliantly treated by Mr. Huxley.[1] He is chiefly concerned with the value of consciousness to an organism—a question into which I cannot enter. What concerns us now is that, however we use the doctrine of continuity, it gives support to belief in a psychic element in plants. All I contend for at this moment is that there is nothing unscientific in classing animals and plants together from a psychological standpoint. For this contention I may quote a well-known psychologist, Dr. James Ward,[2] who concludes that mind "is always implicated in life." He remarks, too (*ibid.* p. 287), "it would be hardly going too far to say that Aristotle's conception of a plant-soul . . . . is tenable even to-day, at least as tenable as any such notion can be at a time when souls are out of fashion."

This is a path of inquiry I am quite incapable of pursuing. It would be safer for me to rest contented with asserting that plants are vegetable automata, as some philosophers are content to make an automaton of Man. But I am not satisfied with this resting-place. And I hope that other biologists will not be satisfied with a point of view in which consciousness is no more than a bye-product of automatic action, and that they will in time gain a definite conception of the value of consciousness in the economy of living organisms. Nor can I doubt that the facts we have to-night discussed must contribute to the foundation of this wider psychological outlook.

LESSONS FROM GERMANY.

WE are glad to see that many public men are directing attention to the relationship between scientific investigation and industrial progress, and urging reforms which were advocated in these columns, and by men of science generally, long before the present position was reached. There is no question now that resolute efforts must be made if Great Britain is to hold her own during the twentieth century. Already we have lost supremacy in several branches of industry, and we shall probably be surpassed in others by America and Germany unless our commercial men learn to realise that science is the source of energy of all sustained industrial movements.

It is the business of scientific research to extend natural knowledge, and the investigator is not usually concerned with the commercial aspects of his work. The application of scientific results to industrial developments is for the manufacturer and merchant to consider, but they are unable to appreciate the possibilities of such results unless they have themselves had a scientific education. A discovery which to one man appears trivial may be made by another the nucleus of a great industrial development. Commercial history can afford numerous instances of the connection between science and prescience and the influence which the two combined exert upon progress. Mr. R. B. Haldane, M.P., mentions a few cases of this kind in an article in the November number of the *Monthly Review.* He selects the brewing industry as one instance of a change which should cause national concern. Thirty years ago Germany exported no beer, to-day she exports almost as much as Britain. The advance is due to the discovery and application of scientific method. When the "Brauerbund" was formed, it was definitely decided to make science with practice and practice with science the principle to work upon. Scientific stations were established in which technical problems confronting the practical brewer could be studied, brewing schools were founded, each with laboratories, experimental maltings and a brewery attached to them, and every effort was made to provide for the education of brewers with scientific as well as technical knowledge. The result of this thorough provision for educating scientific brewers is that German beer is a very active rival of English beers in our own country, and in France it almost monopolises the market.

This is one example given by Mr. Haldane to show how the industrial life in Germany is in close contact with the academic life. The case of the aniline dyes is too well known to need to be described here again, but our loss may be understood by the fact that 80 per cent. of the coal-tar colours used by the Bradford Dyers' Association now comes from Germany.

[1] "Science and Culture," Collected Essays, i.
[2] *Loc. cit.* p. 288.

It is, however, not only through the school that the man of science in Germany comes to the aid of industry, but also through the experiment stations or central bureaus of scientific opinion. The German, remarks Mr. Haldane, "is aware of the enormous extent to which he is dependent upon high science, and, further, that the best high science cannot be bought by the private firm or company. Accordingly the rival German explosives manufacturers several years ago combined to subscribe about 100,000*l.* and to found close to Berlin what they call their Central-Stelle. This establishment, which is maintained by subscription at a cost of about 12,000*l.* a year, is presided over by one of the most distinguished professors of chemistry in the University of that city, with a staff of highly-trained assistants. To it are referred as they arise the problems (in this industry these abound) by which the subscribers in their individual work are confronted. By it is carried on a regular system of research in the field of production of explosives, the fruits of which are communicated to the subscribers."

Compare this organised system of determining the best methods and processes with the narrow spirit in which most of our commercial work is carried on. Trade rivalry exists in Germany as much as here, but it does not prevent combination having for its object the scientific study of subjects related to industries and manufactures.

The universities, technical schools and other academic institutions are all part of an organised system, and though the aim is culture, the application of the highest knowledge to commercial enterprise is borne in mind, and everything is done to encourage it. It is not necessary for us to copy Germany in everything, but we need more of the spirit which has built up such a splendid system of study and brought science, education and industry into such close relationship. It is the duty of the State to do far more than it has hitherto done to promote this connection by assisting research, organising and extending scientific education, and encouraging men to devote their lives to the extension of natural knowledge.

THE BICENTENNIAL OF YALE UNIVERSITY.

THE two hundredth anniversary of the foundation of the University was celebrated by a series of imposing ceremonies at the end of last month. Representatives were present from many universities and colleges, and addresses of congratulation upon the past performances and future promise of Yale were read.

The following is the address written by the Public Orator, Dr. Sandys, and presented to Yale University by the delegates appointed to represent the University of Cambridge at the recent celebration. The delegates appointed were Sir Robert Ball, Fellow of King's and Lowndean professor of astronomy, the Hon. W. Everett, formerly of Trinity College (author of lectures "On the Cam," delivered in Boston, 1865), and Mr. John Cox, late Fellow of Trinity, professor of physics at Montreal. Sir Robert Ball was unavoidably prevented from attending the celebration.

"Litteris vestris, viri nomine non uno nobis coniunctissimi, trans oceanum Atlanticum ad nos nuper perlatis libenter intelleximus, Universitatem vestram, inter Musarum sedes transmarinas prope omnium vetustissimam, annis iam ducentis ab origine sua feliciter exactis, sacra saecularia paucos post menses esse celebraturam. Trans oceanum illum, non iam ut olim dissociabilem, plus quam sexaginta (ut accepimus) ante originem vestram annis, Insulae Longae e regione, Fluminis Longi inter ripas, Britannorum coloni Portum Novum invenerunt, ubi postea Collegio vestro antiquo nomine novo indito civis Londiniensis liberalitatem etiam illustriorem effecistis. Ergo et animi nostri fraterni in testimonium, et diei tam fausti in honorem, tres viros amicitiae foederi novo vobiscum feriundo libenter delegimus, primum Astronomiae professorem nostrum facundum, quem quasi nuntium nostrum sidereum, velut alterum Mercurium Pleiadis filium Atlantis nepotem, trans maria ad vos mittimus; deinde, e vestra orbis terrarum parte, non modo Universitatis Cantabrigiensis utriusque alumnum, cuius eloquentia olim Cami nostri nomen Angliae Novae inter cives magis notum reddidit, sed etiam Universitatis nostrae alumnum alterum, qui provinciae Canadensis Universitatum inter professores numeratur. Has igitur litteras a legatione nostra ad vos perferendas Mercurio nostro tradimus, in quibus Universitati vestrae florentissimae propterea praesertim gratulamur, quod

nuper tam insigne vivacitatis documentum dedistis, ut ex alumnis vestris, quos quindecim milium ad numerum per annos ducentos laurea vestra coronastis, partem plus quam dimidiam adhuc inter vivos numerare potueritis. Valete atque etiam in posterum plurimos per annos felices vivite."

The doctorate of laws was conferred on President Roosevelt and forty-six others, including the following men of science and college presidents:—Prof. J. H. Biles (Glasgow), Dr. J. S. Billings (New York), President C. W. Dabney (Tennessee), Prof. D. W. Finlay (Aberdeen), Prof. Jacques Hadamard (Paris), Dr. S. P. Langley (Smithsonian Institution), Prof. A. A. Michelson (Chicago), Prof. W. Osler (Baltimore), President H. S. Pritchett (Massachusetts), President Ira Remsen (Baltimore), Prof. O. N. Rood (Columbia University), Prof. Wilhelm Waldeyer (Berlin), President J. B. Angell (Michigan), Principal William Peterson (McGill University), Mr. Seth Low (ex-president of Columbia University), President J. G. Schurman (Cornell), Mr. Franklin Carter (ex-president of Williams College), President W. R. Harper (Chicago), Mr. W. C. Harrison (Pennsylvania), President F. L. Patton (Princeton), President B. I. Wheeler (University of California).

On October 22, Dr. D. C. Gilman, a graduate of Yale, and for twenty-five years president of the Johns Hopkins University, delivered an address on the relations of Yale University to letters and science. The address is published in full in *Science* of November 1, from which we select a few notes on men of science who have been connected with Yale.

The Collegiate School of Connecticut was the beginning of Yale University; it became Yale College in 1718, and about the beginning of the nineteenth century developed into the University. During the last fifty years two new schools have sprung into existence—the Sheffield Scientific School and the School of Fine Arts—and the former has increased in importance in a most remarkable manner.

Prior to the Revolution the two men of more than provincial fame whose names are associated with Yale are Edwards, the naturalist, and Eliot. Before Yale College was fifty years old, Benjamin Franklin became its valued friend and was enrolled among its laureati in 1753. Four years previously he had presented the College with an electrical machine which enabled the young tutor, Ezra Stiles, to perform the first electrical experiments tried in New England. A Fahrenheit thermometer was a subsequent gift, and his influence led the University of Edinburgh to confer upon Stiles a doctor's degree.

At the dawn of scientific activity in New England the commanding and attractive figure of Manasseh Cutler stands out. Cutler, a man of the true scientific spirit, an observer of the heavens above and of the earth beneath, is the father of New England botany. He made a noteworthy contribution to the memoirs of the American Academy, collected and described between three and four hundred plants of New England, and left seven volumes of manuscript notes, which are now in the Harvard herbarium, awaiting the editorial care of a botanical antiquary.

Among others whose names are renowned in the world of science are Silliman, leader in chemistry, mineralogy and geology, equalled only by Agassiz; Olmsted, the patient, inventive instructor, whose impulses toward original investigation were not supported by his opportunities; Loomis, interpreter of the law of storms and master of the whirlwind; Dana, the oceanographer; Newton, devoted to abstract thought, who revealed the mysteries of meteoric showers and their relation to comets, not before suggested; and Marsh, the inland explorer, whose discoveries had an important bearing on the doctrine of evolution—these all, with the brilliant corps of the Sheffield Scientific School, were men of rare ability who expounded and illustrated the laws of nature with such clearness and force that the graduates of Yale are everywhere to be counted as for certain the promoters of science.

Two agencies are conspicuous in the second era of Yale, the *American Journal of Science* and the Sheffield Scientific School. Benjamin Silliman showed great sagacity when he perceived, in 1818, the importance of publication, and established of his own motion, on a plan that is still maintained, a repository of scientific papers, which through its long history has been recognised both in Europe and in the United States as comprehensive and accurate; a just and sympathetic recorder of original work; a fair critic of domestic and foreign researches; and a constant promoter of experiment and observation. In the profit and loss account, it appears that the College has never contributed to the financial support of the journal, but it has itself gained reputation from the fact that throughout the world of science Silliman and Dana, successive editors from the first volume, have been known as members of the faculty of Yale.

Agricultural science in the United States owes much to the influences which have gone out from the Sheffield School. J. P. Norton, J. A. Porter, S. W. Johnson, and W. H. Brewer are the followers in our generation of Jared Eliot, the colonial advocate of agricultural science.

In the thirties of last century there was an informal association which may be called a voluntary syndicate for the study of astronomy; and the example and success of these Yale brethren initiated that zeal for astronomical research which distinguishes America. The Clark telescope, acquired in 1830, was then unsurpassed in the United States. One of its earliest and noteworthy revelations was the appearance of Halley's comet, which was observed, from the tower in the Athenæum, weeks before the news arrived of its having been seen in Europe. This gave an impulse to observatory projects in Cambridge and Philadelphia, and college after college soon emulated the example of Yale by establishing observatories in embryo, for the study of the heavens. The most brilliant luminary in the constellation was E. P. Mason, a genius, who died at twenty-two, having made a profound impression on his contemporaries by discoveries, observations, computations and delineations. Under the leadership of Olmsted, Herrick, Bradley, Loomis and Hamilton L. Smith were associate observers, and they were afterwards reinforced by Twining, Lyman and Newton. Chauvenet became a writer and teacher of renown, and Stoddard carried to the Nestorians the telescope that he had made at Yale under the syndicate's influence.

In the science of mineralogy Yale has long maintined the American leadership. No one is likely to overestimate the influence of the collection in the Peabody Museum upon the mind of James D. Dana, nor to overestimate the value of his treatise on mineralogy which, revised and enlarged by able cooperators, continues to be a standard text-book in every country where mineralogy is studied. In view of its recent acquisition, the Museum may almost be described as the "House of the Dinosaur." Its choice collections give an epitome of the sciences of mineralogy, crystallography, meteoroids, geology, palæontology and natural history, from the days of Silliman to those of the Danas, Brush, Marsh and Verrill.

In controversial periods the attitude of Yale has been very serviceable to the advancement of truth. The Copernican cosmography was probably accepted from the beginning although elsewhere the Ptolemaic conceptions of the universe maintained their supremacy, and the notes which Rector Pierson made on physics when he was a student in Harvard come "between the Ptolemaic theory and the Newtonian" (Dexter). When geology became a science, its discoveries were thought to be in conflict with the teachings of the Scripture. Silliman stood firm in the defence of geology, and although some of the bastions on which he relied became untenable, the keep never surrendered, the flag was never lowered. When the modern conceptions of evolution were brought forward by Darwin, Wallace and their allies, when conservatists dreaded and denounced the new interpretation of the natural world, the wise and cautious utterances of Dana at first dissipated all apprehensions of danger and then accepted in the main the conclusions of the new biological school. Marsh's expeditions to the Rocky Mountains and his marvellous discoveries of ancient life made the Peabody Museum an important repository of geological testimony to the truth of evolution.

But there are many others whose work has promoted science at Yale, and the next centennial discourse will do justice to them. Among the departed whose careers were made outside the walls of Yale, Percival, the geologist of Connecticut and Wisconsin; J. D. Whitney, the geologist of California; Chauvenet, the mathematician; Hubbard, the astronomer; Sullivant, the chief authority in mosses as Eaton is in ferns; F. A. P. Barnard, the accomplished president of Columbia; Eli Whitney, the inventor of the cotton-gin; and S. F. B. Morse, whose name is familiar from its relation to the electric telegraph—are especially entitled to honourable mention in this jubilee. So is a much older graduate, David Bushnell, the inventor of submarine explosives—the precursor of the modern torpedists.

This is a record of which Yale may well be proud; and the series of volumes which has been issued in commemoration of

the work of the University is really a stupendous monument to activity in all departments of knowledge. We are only concerned with the volumes containing papers from the scientific laboratories, but even these are of far too elaborate a character to be described adequately in this short article. Five volumes have been received, which can only be briefly noticed. Two of these, edited by Prof. F. A. Gooch, contain records of researches carried on in the Kent Chemical Laboratory of Yale University from the opening of the laboratory in 1888 to the present time. In one volume there are fifty-nine papers, and in the other forty-nine, together with a systematic index, index of authors and index of subjects. A consideration of the more familiar phenomena of optics is given by Prof. C. S. Hastings in a volume on "Light," which ought to receive the attention of students of the subject. The laboratory of invertebrate palæontology contributes a volume, edited by Prof. C. E. Beecher, on "Studies in Evolution," containing papers bearing on the investigation and study of the development of a number of invertebrate animals. The papers deal with the origin and significance of spines, structure and development of trilobites, development of the brachiopoda and miscellaneous studies in development. The fifth volume which has reached us is edited by Profs. S. L. Penfield and L. V. Pirsson, and it contains papers on the results of researches in mineralogy and petrography made in the Sheffield Scientific School of the University. The man of science needs no better evidence of the life and progress of a university than is afforded by volumes like these, which are published in New York by Messrs. Charles Scribner's Sons, and in London by Mr. Edward Arnold.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The president of Magdalen (Mr. T. H. Warren), who has always taken an active part in furthering the interests of science, has been elected a member of the Hebdomadal Council. Prof. Elliott has been elected a delegate of the University Museum.

CAMBRIDGE.—Dr. L. E. Shore, St. John's, has been reappointed University lecturer in advanced physiology, and Mr. F. F. Blackman, St. John's, University lecturer in botany. Mr. H. O. Jones, Clare, has been appointed demonstrator in organic chemistry to the Jacksonian professor, in place of the late Mr. Spivey. Mr. C. Shearer, advanced student, Trinity, has been appointed to occupy the University table in the Naples zoological station.

MR. W. MAITLAND (Aberdeen) has been appointed junior demonstrator of chemistry at University College, Sheffield, in succession to Dr. T. S. Price.

THE Report of the work of the Examinations Department of the City and Guilds of London Institute again directs attention to the fact that the general education of a large number of students who enter the technological classes is still defective, and they are consequently unable to profit, as they should do, by the special instruction they receive. Insufficient knowledge of the elementary principles of science, and particularly of such subjects as mensuration, geometry and drawing, is a frequent cause of failure of students to pass the examinations in technology. The preliminary course of instruction, and corresponding examinations, arranged by the Institute, provides a partial remedy for this defect; and the recent announcement that the Board of Education is prepared to consider suggestions from schools for grouped courses of instruction in branches of science cognate to certain trade subjects should do something to decrease the number of candidates without a knowledge of scientific principles. The Institute's Examination Committee strongly recommend students to attend courses in geometry, mathematics and elementary science, prior to, or concurrently with, the study of technology and workshop practice. "Technical instruction," it is wisely remarked, "fails altogether of its purpose if the student does not understand the 'why' and the 'wherefore' of the operations he performs. The aim of such teaching as is given in technological classes is not to make expert workmen, but to show how difficulties may be overcome, and how skill in drawing and a knowledge of the principles of science may, with sufficient practice, help to produce expert workmen. It is not the object of the Institute's examinations to test mere skill in workmanship. The craftsman's own work is the best certificate he can produce. But as evidence of training in the principles underlying the practice of his trade, the class certificate in technology has a distinct and recognised value."

THE current number of the *Record*, the organ of the National Association for the Promotion of Technical and Secondary Education, contains several interesting articles. Specimen lessons are given to show how interest in nature-knowledge may be encouraged, and how it may be assisted by Museums. It may be doubted, however, whether any useful purpose is served by creating an animistic attitude in the minds of children studying nature. The following statement, for instance, is, to say the least, misleading: "When the horse-chestnut feels winter coming on, it says to itself—you can hear the branches whispering during any autumn evening—'Dear me, my leaves will begin falling off in a minute, and there are those new leaves and things to see about in the spring; I must begin making buds this very instant.'" The child who is taught on these lines will believe that a hawthorn tree is really able to look ahead to a severe winter, and takes pains to provide plenty of haws for the birds during the forthcoming hard times.

THE funds available for purposes of technical education are the residue received under the Local Taxation (Customs and Excise) Act, direct aid from the rates, and grants from the Public Libraries rate. A Return has been issued showing the extent to which, and the manner in which, local authorities are applying these funds in (A) England, (B) Wales, and (C) Ireland. The results are summarised below, the amount shown for Wales and Monmouth, in line B, being exclusive of the amount—estimated at 43,203*l.*—to be devoted annually to intermediate and technical education under the Welsh Intermediate Education Act, 1889:—

	Total amount expended on technical education during the year 1898–99.	Total amount expended on technical education during the year 1899–1900.	Total amount raised by loan on the security of the local rate under the Technical Instruction Acts (or otherwise) during the years 1898–99 and 1899–1900 respectively.	
			Year 1898–99.	Year 1899–1900.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 8.—Mr. T. H. Blakesley, vice-president, in the chair.—A paper on a voltameter for small currents was read by Dr. R. A. Lehfeldt. The instrument consists of a capillary tube about 25 cms. long completely filled with mercury with the exception of a bubble of mercurous nitrate solution about 1 cm. long placed near the middle of the tube. Connection with the two mercury columns is made by means of platinum wires passing through the side of the tube. To use the instrument it is placed in a vertical position, the anode being at the top, and the quantity of electricity which passes through is measured by the change in volume of either electrode. In a test experiment the change in volume was measured by means of a micrometer, and agreed within 0·6 per cent. with the amount deduced from the known value of the current. It is necessary that the currents should be small, so as to avoid complications due to polarisation. The chairman pointed out that the presence of air in the tube would render the readings inaccurate, and asked if it was necessary to apply any temperature correction. Dr. Lehfeldt said that it was quite easy to seal the tube without admitting air, and the temperature correction was negligible.—A note on a paper by Prof. Fleming and Mr. Ashton entitled "On a Model which Imitates

the Behaviour of Dielectrics," by Dr. J. Buchanan, was read by the secretary. The action of this model depends on the viscosity of a liquid, and the diagrams derived from it show by their form that the motion of the pencil which traced them approximated closely to what may be expressed by the term "motion of a viscous fluid by diffusion." In other words, the displacement curves obtained from the model and their derived velocity curves are of the same form as the graphs of certain solutions of Fourier's well-known equation $\frac{dv}{dt} = K\frac{d^2v}{dx^2}$. Lord Kelvin has shown that the potential and the current at any point in the wire of a cable can be expressed by appropriate solutions of this equation, and in the same manner by the use of solutions of this equation the diffusion of electricity into or out of the dielectric of a condenser can be treated. It appears, therefore, that the motion of the model and the diffusion of electricity in a dielectric are subject to one and the same mathematical law. The author suggests that the inventors should obtain hysteresis diagrams by cyclical loading of the springs. Prof. J. A. Fleming said he was glad that Dr. Buchanan had drawn attention again to the model because there were points about it which might be amplified with advantage. After giving a short description of the apparatus he said that Dr. Buchanan had shown that mathematically the theory of the model was the same as that of diffusion in a cable, and he suggested that there might be something more than mathematical analogy. Prof. Fleming referred to the discussion on the original paper in which Prof. Ayrton asked in what respect the model served its purpose better than a twisted wire. A twisted wire cannot represent the properties of a dielectric, because if twisted beyond the elastic limits there is a permanent set. There is no permanent set in the present model. He would like to know if a dielectric has a true conductivity, and suggested that experiments should be made by subjecting a dielectric to constant electric pressure at constant temperature, for years if necessary, and observing whether the curve of current becomes asymptotic to the zero line or to a line parallel to it. The model could be made to represent a conduction as well as a displacement current by so arranging the bottom piston that it could descend but not return. The fact that the movements of the model were similar to the diffusion of current in a cable suggested that the process of conduction in a metal was *similar* to that of displacement in a dielectric.—Mr. J. Macfarlane Gray read a note on the numerical value of the "characteristic" of water. The author referred to a paper on thermodynamics which he wrote twenty years ago and in which he supported the theory of a granular ether under enormous pressure. This theory easily explains the properties of bodies. There is a numerical characteristic for every substance in the state of vapour. This characteristic can be deduced from an analytical expression involving certain physical data which must be experimentally determined. His original number for water was 25·30693, but later experiments by Lord Rayleigh on the weight of hydrogen have altered this number to 25·33776. The author's original value for the absolute specific heat of water was 124960 "mms. lift at Paris," but recent experiments of Callendar give 126230. According to the author's theory, water commences to freeze at 95° F. and the variation of the specific heat of water at low temperatures is due to the latent heat of ice. The formation of ice particles also explains the peculiar changes in volume of water as it cools to the freezing point. The chairman asked if this theory could explain the fact that water can remain liquid below 32° F. Mr. Macfarlane Gray said it could.

PARIS.

Academy of Sciences, November 4.—M. Bouquet de la Grye in the chair.—On *Analysis situs*, by M. H. Poincaré.—On some chemical effects produced by the radium radiation, by M. Henri Becquerel. It is pointed out that the radium radiations consist of a part capable of deviation in the magnetic field, identical with the kathode rays, and a part non-deviable, a fraction of which is absorbable and the remainder extremely penetrating. Some kind of spectrum analysis is, therefore, necessary before studying the chemical action of these rays. Fresh observations are brought forward showing the action of the rays upon glass, the transformation of yellow into red phosphorus, the reduction of mercury perchloride in the presence of oxalic acid and the effect upon seeds. In the latter case it was found that prolonged exposure to the radium radiations had the effect of destroying the power of germinating in the seed.—The electrolysis of ammonium chloride in solution in liquefied ammonia, by M. Henri Moissan. Liquid ammonia at −80° C. is readily electrolysed with a potential difference of 115 volts, and it is remarkable that no nitrogen is produced. At the positive pole chlorine is evolved, and at the negative pole hydrogen, the purity of the latter being proved by analysis. Dry iodine is not attacked or dissolved by liquid ammonia at −70°, or at temperatures below this, but at higher temperatures the iodine goes into solution.—The decomposition of calcium-ammonium and of lithium-ammonium by ammonium chloride, by M. Henri Moissan. Both calcium-ammonium and lithium-ammonium react upon ammonium chloride in solution in liquid ammonia at a temperature of −80° C. Under these conditions the group ammonium could not be isolated, ammonia and hydrogen being set free.—On a new method of detecting very small electric charges, by M. R. Blondlot. Attempts were made, without success, to determine some very small electric charges by means of the usual electroscopes and electrometers. A new instrument was, therefore, constructed, details of which are given, possessing the required sensibility.—The sugars in the blood and their glycolysis, by MM. Lepine and Boulud. It is shown that the difference between diabetic blood and normal blood consists not only in the fact that the former preserves its reducing power better than the latter, but also in the decisive fact that after keeping for an hour in glass vessels at 39°, the fermentable sugar of the blood is not modified, whilst it is destroyed in normal blood.—Remarks by M. Marey on two reports on chronophotography and of a commission on physiology and hygiene.—Report by a committee appointed to examine the papers left by the late M. Halphen. The memoirs left in a state fit for publication are too few in number to publish in volume form, but it is desirable that some periodical would insert certain fragments.—Observations of the 1901 comet made at the Observatory of Santiago, Chili, and the elements of the same comet, by M. Obrecht.—Sunspots and planets, by M. Birkeland. The results given in a former paper have been recalculated, taking into account the action of the planet Saturn, but the conclusions previously arrived at are not thereby altered.—On persistent conjugated network, by M. J. Raffy.—On the adiabatic curve, by M. George Moreau. The usual equation to the adiabatic curve, $PV^{\gamma} =$ const. is obtained under the suppositions that the ratio of the specific heats, the specific heat at constant volume and the coefficient of expansion are constant. It has been shown, however, by MM. Mallard and Le Chatelier that the specific heat at constant volume is not constant, but is a linear function of the temperature, and the coefficient of expansion is also a function of the temperature. On these assumptions a more general form of the equation to the adiabatic curve is worked out.—On the chlorobromides of thallium of the type Tl_4X_6, by M. V. Thomas. The current theories of the constitution of double salts would allow of the prediction of two sesquichlorobromides of thallium. The mode of preparation of two isomers of $Tl_4Cl_3Br_3$ is described in detail.—Some reactions of trichloracetic acid, by M. A. Clermont. The ethyl ester and amide of this acid are so readily prepared that their formation may be used as tests for the acid.—Researches on some isomerides of pinacone and its derivatives, by M. Maurice Delacre. The reactions of pinacoline agree in part with the formula suggested by Butlerow $(CH_3)_3.C.CO.CH_3$, and in other respects corresponds to Friedel's formula $\overbrace{(CH_3)_2C\text{——}C}^{O}\text{—}(CH_3)_2$. As a result of the experiments here given the author inclines to the view that pinacoline contains the two substances represented by the above formulæ in a state of equilibrium.—The constitution of piceol, by MM. Ernest Charon and Démétrius Zamanos. The glucoside piceine, extracted by M. Tanret from *Pinus picea*, was shown by him to be hydrolysed by acids into glucose and a substance piceol. It is now shown that this latter substance is paraoxyacetophenone, the properties of the natural and synthetical piceols agreeing completely.—On the calculation of the amounts of water added to and cream abstracted from milk, by M. V. Génin.—On the formation of the perfume of vanilla, by M. Henri Lecomte. The following hypothesis would best appear to explain the formation of vanillin in the fruits during their preparation. The coniferine is converted into coniferyl alcohol and glucose by means of a hydrolytic ferment, crude vanilla, in fact, always containing glucose. This alcohol is then transformed into vanillin by the action of an oxydase, the existence of

which has been proved in the plant extracts in several ways. It is a curious fact that the varieties which are the most esteemed commercially are those which contain the greatest amount of this oxydase.—On the *Iboga*, on its exciting properties, its composition, and on the new alkaloid, ibogaine, which it contains, by MM. J. Dybowski and Ed. Landrin. A plant much used by the natives in the French Congo, and called by them *iboga*, has been found to owe its sustaining and fatigue-resisting properties to the presence of a new alkaloid, ibogaine, to which the constitution $C_{52}H_{66}N_6O_2$ is assigned. In small doses this substance produces a peculiar excitement, in large doses the effects resemble those due to the absorption of alcohol in excess.—The influence of methylal upon the growth of some algæ in soft water, by M. Raoul Bouilhac. Certain algæ, nostoc and *Anaboena*, were placed in nutritive solutions and exposed to light of feeble intensity, too feeble to enable the algæ to decompose carbonic acid; it was found that under these conditions growth could take place if a small quantity of methylal were present.—Researches on the formation of the ovule and the embryonic sac in the Araliaceæ and of the modifications undergone by the tegument, by M. L. Ducamp.—The germination of the spores of *Penicillium* in water, by M. Pierre Lesage.—The effects of freezing upon milk, by MM. F. Bordas and de Raczkowski.—On the secular variations of terrestrial magnetism, by M. V. Raulin.—Experiments in maritime aëronautics, by M. H. Hervé.

NEW SOUTH WALES.

Linnean Society, September 25.—Mr. J. H. Maiden, president, in the chair.—Arachnida from the South Seas, by W. J. Rainbow. Thirty-four species are enumerated, of which four are described as new, namely, *Leptodrassus insulanus*, *Argyrodes walkeri*, *Diaea bipunctata* and *D. regale*. The most interesting of them is *L. insulanus*, as it records a new locality for the genus.—On the systematic position of *Purpura tritoniformis*, Blainv., by H. L. Kesteven. Reasons are given for removing *P. tritoniformis* from *Urosalpinx* and *Cominella* and transferring it to *Purpura*. In selecting the subgenus of the latter for its reception, the resemblance of the larval shell and anatomical characters to *P. succincta* cause the writer to place it in *Trochia*. The names *Adamsia* and *Agnewia* consequently lapse into the synonymy of *Trochia*.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 14.

MATHEMATICAL SOCIETY, at 5.30.—Linear Groups in an Infinite Field: Dr. L. E. Dickson.—Note on the Algebraic Properties of Pfaffians: J. Brill.—On Burmann's Theorem: Prof. A. C. Dixon.—The Puiseux Diagram and Differential Equations: R. W. H. T. Hudson.—Determination of all the Groups of Order 168: Dr. G. A. Miller.—An Outline of a Theory of Divergent Integrals: G. H. Hardy.—On the Representation of a Group of Finite Order as a Permutation Group; and on the Composition of Permutation Groups: Prof. W. Burnside, F.R.S.—(1) On the Inversion of Plane Stress; (2) On the Theory of Hele-Shaw's Experiments on Fluid Motion: J. H. Michell.—On the Steady Motion of a Sphere through Viscous Liquid: T. Stuart.—Addition Theorems for Hyperelliptic Integrals: A. L. Dixon.—Limits of Logical Statements: H. MacColl.

FRIDAY, NOVEMBER 15.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—The President, Dr. Patrick Manson, C.M.G., F.R.S., will deliver his Inaugural Address on the Ætiology of Beriberi.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.

TUESDAY, NOVEMBER 19.

ZOOLOGICAL SOCIETY, at 8.30.—Okapia, a New Genus of Giraffidæ from Central Africa: Prof. E. Ray Lankester, F.R.S.—On the Giraffe discovered by Sir Harry Johnston, K.C.B., near Mount Elgon, Central Africa: Oldfield Thomas, F.R.S.—On the Genital Organs of the Male Lepidosiren and Protopterus: J. Graham Kerr.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*: The Discharge of Sewage into a Tidal Estuary: W. Kaye Parry and Dr. W. E. Adeney.—*And, time permitting*: The Treatment of Trades Waste Bacterially: William Naylor.

ROYAL STATISTICAL SOCIETY, at 5.30.—Local and Imperial Burdens: Lord Avebury, F.R.S.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Japan as illustrated by Herself: J. W. Groves.

WEDNESDAY, NOVEMBER 20.

GEOLOGICAL SOCIETY, at 8.—On the Origin of Certain Concretions in the Lower Coal Measures: H. B. Stocks.—Some Remarks on the Meteorological Conditions of the Pleistocene Epoch: Nils Ekholm.—Notes on the Genus Lichas: F. R. C. Reed.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—The Exploration of the Atmosphere at sea by means of Kites: A. Lawrence Rotch.—Meteorological Phenomena in relation to the Changes in the Vertical: Prof. John Milne, F.R.S.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Stereomicrography: Prof. G. P. Girdwood, preceded at 7.30 by an Exhibition of some Antipoints seen under the Microscope: Conrad Beck.

SOCIETY OF ARTS, at 8.—Opening Address: Sir William Henry Preece, K.C.B., F.R.S.

ENTOMOLOGICAL SOCIETY, at 8.

THURSDAY, NOVEMBER 21.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On Skin-currents. Part II. Observations on Cats: Dr. Waller, F.R.S.—The New Biological Test for Blood in relation to Zoological Classification: Dr. G. H. F. Nuttall.—Observations on the Cerebral Cortex of the Ape (Preliminary Communication): A. S. F. Grünbaum and Prof. Sherrington, F.R.S.—On the Inheritance of the Mental Characteristics in Man: Prof. K. Pearson, F.R.S.

LINNEAN SOCIETY, at 8.—Report on the Botanical Publications of the United Kingdom as a Part of the International Catalogue of Scientific Literature: B. Daydon Jackson.

SUPPLEMENT TO "NATURE."

A MODERN TEXT-BOOK OF CHEMISTRY.

Roscoe-Schorlemmer's ausführliches Lehrbuch der Chemie. By Jul. Wilh. Brühl, Professor in the University of Heidelberg. Vol. vii. Part v., and Vol. viii. Part vi., Organic Chemistry, in cooperation with Eduard Hjelt and Ossian Aschan of the University of Helsingfors. Pp. xxvii + 1320 and xxxix + 1045. (Brunswick: Friedrich Vieweg und Sohn, 1899-1901.)

THE well-known treatise on chemistry by Roscoe and Schorlemmer, which has for so many years been a standard work in this country, is now being published in a totally revised form in Germany, and two parts of the German edition have been received for review. The preceding (sixth) volume, containing an account of the heterocyclic five-membered rings, was published in the spring of 1898, the seventh in July 1899, and the eighth in May of the present year. The ninth and concluding volume, dealing with albuminoid compounds, ptomaines, toxines and enzymes, is promised in a few months' time, so that the work has been pushed on with remarkable rapidity. Certain sections, moreover, such as the portions dealing respectively with the vegetable alkaloids and albuminoid compounds, have been published as separate monographs, the former having already been noticed in these columns by the present writer.

Taking the two volumes before us in due order, the seventh, which consists of 1320 closely printed pages, is devoted to the six-membered heterocyclic ring compounds. These comprise the pyrone, pyridine, quinoline and isoquinoline groups and their hydro-derivatives, the alkaloids related to this class, the azines, the uracil and purine compounds, the pyrazines, piperazines, quinoxalines, azine colouring-matters, kyanidines, cyanuric acid derivatives, &c. Dr. Brühl, in his prefatory notice, calls attention to the fact that the whole of this enormous mass of material has been worked up within the short period of one year, the editorial work having been concluded towards the beginning of 1899. The section on the metallic compounds of pyridine, which occupies twenty-two pages, has been contributed by Prof. Alfred Werner, of Zürich, while Prof. Emil Fischer has revised the portion relating to the purine group. We are further told in the preface that the aim of the authors has been, not only to present a complete, but also a *readable* account of modern organic chemistry, and each chapter accordingly commences with a concise but thorough historical introduction, which will be found most interesting by all who desire to follow the steps by which our knowledge of the different groups has been built up.

Comparing the present work with its English predecessor, it will be seen that the rapid development of organic chemistry has necessitated much more than mere revision. Whole sections have been re-written, and but little of the original "Roscoe and Schorlemmer" beyond the general plan is left. That this work of compilation and coordination has been carried out most thoroughly and efficiently is sufficiently guaranteed by the names of Dr. Brühl and his coadjutors. In view of the great advance of the science of chemistry in every direction, it is practically impossible to produce a text-book, however complete, which can be expected to survive for more than a limited period. Such a work as that under consideration must be considered as presenting a complete epitome of the science down to the date of its publication; and as a standard of reference for students and workers it may be confidently asserted that it is destined to have a long and useful career. How many years will elapse before a new edition is called for—whether it will be possible to keep pace with the progress of discovery by the issue of supplementary volumes, whether it may not be necessary to revise particular volumes from time to time—these are questions of procedure to which time and the exigencies of the German publishing trade can alone give a reply. But if the reader who, without being a specialist in this department of chemistry, is interested in a general way in the development of our knowledge of the carbon compounds will make such a comparison as is here suggested, he cannot fail to be struck by the manifest indications of ceaseless activity on the part of investigators in this practically inexhaustible domain. Take, for example, the purine group, which has been attacked with such brilliant success by Emil Fischer and his pupils. It is about seventeen years ago since Fischer's first communication on this subject, and at the present time it may be said that our knowledge of the constitution of all the physiologically important members of the group is fairly complete, and what makes this chapter of research so particularly interesting is that not only have the majority of these products of animal and vegetable life been synthesised, but a large number of new purine derivatives which have never been elaborated by "vital" processes have been called into existence by virtue of that mastery over the chemical molecule which invariably follows when the constitution of the type has been established. From the same point of view the pyrone group is likewise of special interest. Colouring-matters, such as chrysin, from the buds of various species of *Populus*; apigenin, which occurs as a glucoside in parsley; fisetin, from *Rhus cotinus*, *R. rhodanthema* and *Quebracho colorado*; luteolin, from *Reseda luteola*; kampheride, from the Chinese galanga root (*Alpinia officinarum*); quercetin, which occurs as a glucoside in quercitron bark (*Quercus tinctoria*) and in many other plants; rhamnetin, from buckthorn berries, &c.; isorhamnetin, from the wall-flower; morin, from fustic; euxanthone, from Indian yellow; gentisin, from the root of *Gentiana luteola*, and other well-known and definite products of vegetable origin are now known to belong to the benzo-γ-pyrone and dibenzo-γ-pyrone types. In establishing the constitution of these compounds A. G. Perkin, of the Yorkshire College, has taken an important part. Only two years ago the authors of the present volume were obliged to state, in summing up our knowledge of the benzo-γ-pyrones, that "none of these natural colouring-matters have as yet been synthesised" (p. 49). Of the dibenzo-γ-pyrone (xanthone) group, euxanthone had been synthesised by Liebermann in 1889 and gentisin by v. Kostanecki and Tambor in 1894. Since the appearance of the present volume the synthetical production of chrysin, apigenin and other natural colouring-matters of the same group has been

announced from time to time by v. Kostanecki and his colleagues. It is not improbable that before many years have elapsed the above statement concerning the benzo-γ-pyrones will have to be modified so as to read in the exactly opposite sense.

In calling the attention of English chemists to the present edition we cannot too strongly emphasise the point that the eminently readable character of the original "Roscoe and Schorlemmer" has been greatly enhanced by the revision which it has undergone in Germany. It is not only the historical treatment which makes the book such interesting reading, but the logically coherent way in which the descriptive facts and theoretical deductions are marshalled so as to lead the reader step by step from the first discovery of a compound up to the latest constitutional formulæ for the whole group. The evidence which has led to the adoption of any particular formula is given in detail, with bibliographical references in the foot-notes. If educationists of the old school should at any time challenge (as they have before now) the value of modern science as a mental discipline, we may confidently ask them to place this book in the hands of a student who has mastered the elementary principles of chemistry and request him to read conscientiously through any one of the sections and follow the work which the investigators have carried out in arriving at the results given. If after this he is not inspired with a desire to become a worker himself, or if he fails to see the logical connection of the various discoveries which have culminated in the present state of knowledge, his case may be dismissed as hopeless, and some non-chemical career recommended.[1]

The general plan of the English original is, of course, well known in this country; but it may be useful in connection with the above eulogistic statements to invite attention to the details of treatment of one or two groups taken at random. On p. 80, for example, there commences the section dealing with six-atom rings containing one nitrogen atom. This section comprises seven groups, viz. pyridine and homologues and isomerides; hydropyridines; quinoline and homologues and hydro-derivatives; the acridine group; phenanthridine and chrysidine group; quino-quinoline and naphthinoline group; and the isoquinoline group. The first only of these need be taken by way of illustration. The occurrence of the pyridine bases from the historical point of view is first considered, and a summary of the early work of Runge, Hofmann, Thomas Anderson and other investigators of "Dippel's oil" and the coal-tar bases is given in chronological order. A short paragraph on the mode of formation of pyridine bases by the destructive distillation of animal matter explains the theory first promulgated by Weidel and Ciamician that the bases originate in this process from unsaponified fats, the glycerol complex being essential for the pyrogenic synthesis of the bases. Then follows a section on the separation of the bases from bone-oil and from coal-tar, the so-called "light oil" of the latter being at present the chief source of pyridine and its homologues.

[1] A distinguished mathematician known to the writer used to take great pleasure in reading original papers on organic chemistry, although he had no practical acquaintance with the science. He considered the methods of arriving at constitutional formulæ as masterpieces of scientific reasoning.

The discussion of the constitution of pyridine occupies nine pages, full consideration being given to this subject on account of the important position which this base holds as the type of a series which comprises so many members and to which many natural alkaloids are related. The first formula considered is that of Körner and Dewar, corresponding to Kekulé's benzene ring formula. Of the various formulæ proposed as alternatives, that of Riedel and of Lieben and Haitinger, in which there is cross linkage between the nitrogen and the opposite γ-carbon atom, is alone considered as having any serious claim. The formulæ corresponding to the "prismatic" and "diagonal" benzene formulæ are dismissed in very brief paragraphs, the latter being considered as disproved by the (unpublished) spectrometric researches of Brühl. The "centric" formula proposed by Bamberger, and corresponding with the centric formula of benzene, is regarded as beyond the possibility of experimental proof, and, like the corresponding benzene formula, is considered to be outside all analogy. On the whole, while admitting that a decisive proof of the constitution is yet wanting, the original formula of Körner is shown to be most in harmony with the known facts and is adopted throughout the work.

The constitutional formula of pyridine—the parent compound of the series—having been thus threshed out, the following section is devoted to the question of isomerism and orientation among the derivatives. The synthetical formation of pyridine compounds is next dealt with. Taking the various methods in the order given, we have the formation of pyridine homologues by heating aldehydes or ketones with aldehyde-ammonia, acetamide, ammonium phosphate, &c., as first observed by v. Baeyer and Ador in 1870; then follows the general method of Hantzsch (1881), which consists in condensing β-keto-compounds (such as acetoacetic ester) with aldehydes and ammonia, and the extension of this method to diketones by Beyer and Knoevenagel (1891 and 1898). Another general method, discovered by Claisen in 1893, consists in the condensation of methenyl derivatives of certain β-diketo-compounds with ammonia. Ladenburg's intramolecular formation of the α- and γ-homologues by the action of heat on pyridinium methyl iodide and the formation of oxypyridines by the action of ammonia on α- and γ-pyrone derivatives are next considered, and attention is directed finally to the remarkable formation of pyridine derivatives from pyrrole and its homologues by the action of halogen-derivatives of methane on the potassium or sodium derivatives of the pyrroles as observed by Ciamician and his colleagues (1885–1887). The mechanism of all these synthetical processes is, of course, explained as far as known and illustrated by formulæ. After a few pages devoted to the general properties of the bases of the series, the description of the individual members is given in exhaustive detail. Beginning with pyridine itself and ending with dipyridyl, this descriptive part extends over 157 pages.

The chemistry of any of the groups dealt with in the present work can be systematically followed out by those who make use of these volumes either for the purposes of reference or in order to make themselves acquainted with the actual state of knowledge down to the date of pub-

lication. The above example is typical of the treatment throughout, and the student or worker may confidently make use of any portion of the vast mass of information crowded into every page as accurate and authoritative. It is interesting to note also how among compounds of industrial importance references to patents figure occasionally in the literary notes. We have on former occasions pointed out that discoveries of first-rate scientific importance are often in the first place published through the Patent Offices, owing to their being also of commercial value.

The larger portion of the eighth volume deals with the vegetable alkaloids, and concerning this we have only to refer our readers to the opinion expressed in the former notice (NATURE, vol. lxiii. p. 486, March 21, 1900). Dr. Brühl states in the preface that this monograph was sent to press in January 1900, and the printing concluded in October of the same year. The volume contains in addition a monograph on vegetable glucosides which occupies 138 pages, sections on bitter compounds (non-glucosidic) and natural organic colouring-matters, and sections amounting to monographs on chlorophyll and the compounds obtained from lichens. The concluding section is devoted to the indifferent or neutral compounds not previously considered. It will be only necessary to indicate very briefly the contents of these sections. The glucosides are classified according to the nature of the complex associated with the carbohydrate residue such as hydrocarbon glucosides (picrocrocin), glucosides of benzophenols, of alcohols, of aldehydes, of acids, of oxy-anthraquinone, of oxyflavone, &c., and those glucosides of which the products of hydrolysis are at present imperfectly known. The neutral bitter principles comprise compounds such as aloin, picrotoxin, podophyllotoxin, cantharidin, &c. The natural colouring-matters are classified as derivatives of pyrone, of benzophenone, of hydrindene, of naphthalene and anthracene, &c. Not the least interesting of this group of compounds are the colouring-matters derived from insects, such as cochineal, lac-dye and kermes, which are classified as hydrindene derivatives. Our knowledge of these compounds has made considerable progress of late years, as will be seen on reading this connected account of the researches of Liebermann and his pupils on carminic acid. So also it may be noted that our knowledge of the constitution of the colouring-matters of logwood, Brazil wood and of other familiar vegetable dye-stuffs has been much advanced by the work of W. H. Perkin, jun., and his colleagues. Should these ever (as is not at all improbable) come within the domain of accomplished syntheses, we might see the last of the vegetable dyes replaced by the products of chemical factories.

The section on chlorophyll is quite remarkable for its completeness, and will appeal not only to chemists, but to physiological botanists and biologists generally. It occupies more than seventy pages and comprises a bibliographical list of no less than nine pages, giving full references to all the papers and memoirs of any importance that have been written on the chemistry of this subject, the arrangement being chronological from the memoirs of Senebier in 1782–1788 down to the latest papers of Marchlewski and Schunck in 1900. Under this section there are comprised not only chlorophyll and its derivatives, but the various yellow colouring-matters which accompany chlorophyll and other related compounds Equally remarkable as a revelation of progress is the long list of lichen products, our knowledge of which has been so largely extended of late years, chiefly through the labours of Hesse and Zopf, who have won for themselves the foremost position as pioneers in this branch of plant chemistry. Nearly 100 distinct compounds of this group have now been isolated and analysed, and considerable progress has been made towards establishing the constitutional formulæ of some of them. Vulpic acid, which occurs in many lichens and which was first isolated in 1831, was synthesised by Volhard in 1894.

The prevailing impression left after looking through the contents of this eighth volume is that its interest will extend to a much wider circle of readers than those who are likely to make use of it from the purely chemical point of view. The immense number of natural products —such as alkaloids, colouring-matters, neutral compounds, chlorophyll, glucosides, lichen products, &c.— described and discussed will make this instalment of the new "Roscoe and Schorlemmer" particularly valuable to physiologists. In the words of Dr. Brühl, who in the preface calls attention to the circumstance that the present volume contains a large amount of material which has now in part undergone systematic chemical investigation for the first time :—

"Wenn dieses Material für den Chemiker mehr als alle bisher behandelten Gruppen noch Unbekanntes enthält, so ist es für den Biologen nicht minder fragenreich und von grosser Bedeutung. In dem rapiden Entwickelungsgange der Naturwissenschaften nähert sich die Chemie in neuester Zeit immer rascher den biologischen Disciplinen, und eine zusammenfassende Bearbeitung derjenigen Gegenstände, welche gegenwärtig diese Wissenszweige beschäftigen und mit der Chemie verknüpfen, wird daher zweifellos Vielen willkommen sein. Es ist in diesem Bande, mit besonderem Hinblick auf die Interessen eines weiteren naturwissenschaftlichen Kreises, zwar stets das Chemische als Hauptaufgabe behandelt, indessen auch das Biologische so weit berücksichtigt worden, als dies in einem chemischen Lehrbuch thunlich erschien."

One serious consideration arising from the publication of the present work is that a standard treatise originally planned and published in this country should now have passed out of our hands. The reading public interested in chemical literature cannot have been sufficiently numerous to warrant the publication of a revised edition in English. On the other hand, we find German chemists of the very highest repute willing to undertake the literary labour and a German firm willing to incur the risk and bear the expense of publication. The writer knows nothing of the cost of printing and publishing in Germany, but the price of the books is not less than that of the original edition in this country (vol. viii., in paper wrappers, is priced at 22 marks), so that it cannot be urged that the German student gets his text-books cheaper than the English student. The natural conclusion would appear to be that a sufficiently large number of readers in Germany can be depended upon to warrant the risk of publication of the work in that language, and this again raises the question whether the kind of scientific

literature in demand in England and Germany respectively may not be taken as an indication of the relative position of science teaching in the two countries. For depth and breadth of treatment, we naturally turn to works like that under consideration—a treatise which the facts before us now declare to be in such little demand here that the English publishers do not feel warranted in undertaking the further responsibility of issuing a revised edition. On the other hand, it may be confidently asserted that there is no other country in the world which of late years has produced such a vast number of little elementary books on chemistry. It is no exaggeration to say that books of this class can be named by hundreds. Almost every newly appointed teacher, lecturer, and professor feels it a duty to contribute to the list of what may in the majority of cases be called little cram books. Thus, while the demand for a substantial work is on the decline, there is apparently an unlimited field for manuals of the kind referred to. The system of wholesale smattering which is so characteristic of the modern educational revival in our country appears to have acted prejudicially upon the chemical literary energy of our authors and publishers, which is thus being frittered away in small efforts directed mainly towards the requirements of examining boards. It has been said with justice that in the domain of fiction magazine writing has been the curse of high-class English literature. It may with equal truth be asserted that writing up to the requirements of examining bodies has been the curse of English chemical literature. The Americans have in recent times shown a great desire to possess good textbooks of science, and their translations of certain German works are in use in this country. It only remains now for some enterprising American to bring out a translation of the new "Roscoe and Schorlemmer" to convert the position into one of ignominy for the country which first contributed this treatise to the literature of modern science.

R. MELDOLA.

PRÆ-ARYAN RELIGION IN GREECE.

Mycenaean Tree and Pillar Cult and its Mediterranean Relations. By Arthur J. Evans. "Journal of Hellenic Studies," vol. xxi. pp. 99*ff.* Pp. xii + 106. (London: Macmillan and Co., Ltd., 1901.) Price 6*s.* net.

FEW discoveries in the archæological field during the past few years have commanded such universal attention and have so profoundly modified our conception of the *origines* of European civilisation as the excavation of the Mycenæan palace and city of Knôssos in Crete by the able and energetic keeper of the Ashmolean Museum at Oxford, Mr. Arthur J. Evans. It is not many years ago since, in spite of the discoveries of Schliemann and his successors at Troy, at Mycenæ and at Tiryns, and of the steadily accumulating evidence from all parts of the Greek world, things "Mycenæan" were still looked at askance, especially by classical archæologists of the older school, who could never accustom themselves to the idea that the classical Greece which they and their forefathers for three centuries back had known by heart was but the *second* phase of Greek life and activity, that long before the First Olympiad Greece had been the seat of a magnificent and luxurious culture of which faint echoes are preserved to us in the Homeric poems, and of which the actual remains still exist upon Greek soil. The treasuries of Minyas and of Atreus still stood above ground, but none seemed to realise their intense interest; Mycenæ still existed off the road from Corinth to Argos, but nobody had thought of looking to see whether it had really been "golden" and "widewayed" until the firm belief of Schliemann in the historical reality of the Trojan War impelled him to go and look. We know what he found, and now, after twenty years, we can appreciate the revolution which he wrought in our conceptions of the earlier ages of Greece. Mr. Evans's Cretan discoveries have rivetted our attention once more upon the antiquities of the "Mycenæan" Age, and now we can see clearly, where before we saw but darkly, that the relics of the First Greece which we can hold between our hands are not those of any problematical "Mycenæan" period, the date of which was but doubtful and was, indeed, not to be too closely investigated lest it upset our traditional ideas too much—are, in fact, the relics of the Heroic Age of Greece. The Heroes existed: and here are their cities, their palaces and their works of art. No such actual personages as Agamemnon or Achilles or Minôs need ever have existed in life, but their magnificent figures undoubtedly represent the great kings who ruled in Mycenæ and the Isles, in Lacedæmon and in Crete, in times which to the Homeric singers were already ancient. The Trojan War is no sun-myth, it is a tradition of an actual occurrence. Theseus may never have actually rescued Ariadne from the Minotaur, but the Labyrinth has been laid bare by the spade of Mr. Evans, and the Cretan kings who are personified by the legendary Minôs undoubtedly lived therein and venerated there a deity to whom the bull was sacred and to whom human sacrifices were very possibly offered in remote days long before the story of Theseus and the Minotaur took shape. And now Mr. Evans has discovered and placed before us the actual hieroglyphed tablets which contain the records, the accounts, the inventories, the registers of the daily transactions of the Minoans of the Heroic Age. We cannot yet read them, but there is no doubt that no energy will be spared to attain this end. We are on the brink of discoveries which may extend our knowledge of the beginnings of Greek, and therefore also of European civilisation, in directions which cannot as yet be guessed at. We may yet read the actual historical records of events of which Greek tradition has preserved to us but distorted and imaginative accounts.

The purpose of Mr. Evans's present monograph is to arrive at some measure of certainty with regard to the religious conceptions of the Heroic Greeks on the basis of the representations of cult-scenes which they have left behind them on gems, rings, vases, &c. It is a difficult task, but one which Mr. Evans has essayed with much success, though it may seem to the reader that his treatment of it is somewhat too voluminous, that, indeed, while reading it is occasionally difficult to see the wood for the trees. This is no doubt due to Mr. Evans's unrivalled power of illustration from Greek legend and his

minute knowledge of even the most out-of-the-way hints in the classical writers which in any way bear upon the problem which he seeks to elucidate; perhaps, therefore, it should be accounted to him as a virtue rather than as a vice. We have said that Mr. Evans has discovered the veritable Labyrinth of Minôs. Unless the reader is well read in the voluminous literature, scattered through a hundred learned periodicals, of Mycenæan archæology, it will perhaps be difficult for him to appreciate all the various items of evidence which render this clear, but it is a fact which it is difficult to dispute. On p. 110 of the work under review Mr. Evans writes:—

> "In the great prehistoric Palace at present partially excavated by me at Knôssos I have ventured on many grounds to recognise the true original of the traditional Labyrinth. It is needless here to speak of its long corridors and succession of magazines with their blind endings, its tortuous passages, and maze of lesser chambers, of the harem scenes painted on its walls, and its huge fresco-paintings and reliefs of bulls, grappled perhaps by men, as on a gem impression from the same site, the Mycenæan prototype of Theseus and the Minotaur. All this might give a local colour to the mythical scenes with which the building became associated. But there is direct evidence of even a more cogent nature. It was itself the 'House of the Double Axe,' and the Palace was at the same time a sanctuary. The chief corner-stones and door-jambs, made of huge gypsum blocks, are incised with the double axe sign, implying consecration to the Cretan Zeus. More than this, in the centre of the building are two small contiguous chambers, in the middle of each of which rises a square column, formed of a series of blocks, on every side of which in one case and on three sides of the other is engraved a double axe (Fig. 5). There can, I venture to think, be little doubt that these chambers are shrines, probably belonging to the oldest part of the building, and the pillars thus marked with the sign of the god are in fact his aniconic images."

Now the double axe is known to us as the symbol of a deity, the Karian Zeus of *Labranda;* it occurs also on Carian coins and on coins of Tenedos, where it is also a god-symbol.

> "With the evidence of this primitive cult of the weapon itself before our eyes," says Mr. Evans (p. 108), "it seems natural to interpret names of Carian sanctuaries like Labranda in the most literal sense as the place of the sacred *labrys*, which was the Lydian (or Carian) name for the Greek πέλεκυς, or double-edged axe. On Carian coins indeed of quite late date the *labrys*, set up on its long pillar-like handle, with two dependent fillets, has much the appearance of a cult-image."

Now we have traditional evidence for the fact that the præ-Hellenic or Eteokretan population of Crete was ethnically connected with the inhabitants of Asia Minor, that it was, in fact, of "kleinasiatisch" stock. Many place-names in south-western Asia Minor end their Græcised forms in -νδα or -νδος, which is generally regarded as a typically Karian and Lycian termination. The Lycian language can be to a great extent read, and we know that a typically Lycian nominal affix was *-ñna*. This is the -νδα, -νδος of the Greek transliteration. Labra-*nda* or Labrau-*nda* is then "The Place of the Double Axe." Now in Crete, originally inhabited by a people ethnically connected with the speakers of Lycian and Karian, we have at Knôssos a legendary *Labyrinthos*, identified with the worship of a Zeus in connection with whom the bull was venerated. Also, one of the Curetes of Cretan legend was named *Labrandos*. Now, as Mr. Evans points out (p. 109), Jupiter Dolichenus, a Commagenian form of the double-axe god of Asia Minor, is represented standing, armed with his axe, *upon the back of a bull*. Further, on a Mycenæan gem from Argos a double axe is seen immediately above a bull's head. It is then evident that in Greece as in Asia the god of the double axe was also the god of whom the bull was an emblem, to whom the bull was sacred. In all cases this god is identified with Zeus. At Knôssos Mr. Evans finds a temple-palace devoted to the service of a god with whom the bull is constantly brought into connection and of whom the double axe is the symbol. It is a "Place of the Double Axe." At Knôssos we have the Labyrinth of legend; Λαβυρι-νθος is then naturally concluded to be the Cretan equivalent of Labra-nda; in the præ-Hellenic "kleinasiatisch" language of Crete the name signified "Place of the Double Axe." The palace of Knôssos is then the veritable Labyrinth of Minôs.[1]

Now the double axe of the Knôssian Zeus is often found on Mycenæan gems placed above a two-horned object, which must, since the axe was an object of worship, be a horned altar. When, therefore, he finds that pillars and trees are often represented in the same position as the axe, above a two-horned altar, Mr. Evans naturally concludes that the Pillar and the Tree were, equally with the Double Axe, objects of veneration to the Mycenæans of Greece proper as well as of Crete. Traces of such worships are, as he exhaustively shows, abundant in classical Greece, and there can be little doubt that in Mycenæan days they flourished exceedingly. When, however, Mr. Evans, rightly ascribing their origin to an "aniconic" period of religious development, proceeds to argue that the religion of the highly-civilised Mycenæans, the progenitors of Greek culture, had remained exclusively aniconic, it may be permissible to join issue with him: because no large Mycenæan idols have *yet* been found, we cannot say that none will ever be found, and we know that the barbaric ancestors of the Mycenæans, the "Præ-Mycenæans" of the "Island-Graves" of the Cyclades, actually did venerate rude marble idols, which are found in their tombs. And glyptic representations of Mycenæan deities are common enough. It seems preferable to hold that while anthropomorphic images of deities were probably made and worshipped by the Mycenæans, at the same time their symbols, the Pillar, the Tree, the Axe, &c., continued to be venerated.

Mr. Evans speaks of the Mycenæan altar-horns as the "Horns of Consecration," and naturally compares this article of religious furniture, as well as the Pillar and the Tree, with the horned altar, the *Maṣṣêbhâh* or sacred stone (*baitylos*), and the *Ăshêrâh* of the Semites. There is obviously a connection here, but, as Mr. Evans points out (p. 131), this connection is by no means necessarily

1 The various portions of the argument will be found discussed in Mr. Evans's monograph, by Mayer ("Mykenische Beiträge," in the *Jahrbuch des kgl. deutschen Instituts*, vii. (1892) p. 191), and in Kretschmer's "Einleitung in die Geschichte der griechischen Sprache," ch. x. p. 289 *ff.*

of the kind which is likely to be assumed by those who are well acquainted with Semitic antiquities but are not aware of the present trend of opinion with regard to the ethnology of the peoples of the Eastern Mediterranean basin. The question is not "Did the Semites influence Mycenæan religion in the matter of Tree and Pillar worship?" but rather "From whom did the Semites derive their Tree and Pillar worship?" The matter is as yet by no means clear, but all the indications, in regard to which archæology, philology, and ethnology, as exemplified in the conclusions of Evans, Kretschmer, and Sergi, concur, point to Aryan Greeks and Phrygians and Semites having been in reality the successors in Greece, north-eastern Asia Minor, and Palestine respectively of a præ-Aryan and præ-Semitic race of the same stock as the inhabitants of the greater part of Asia Minor, who were certainly neither Indo-Europeans nor Semites. It is with these people that the Tree- and Pillar-cults of both Greeks and Semites may have originated. Whether the Mycenæans of Knôssos were pure-blooded members of this præ-Hellenic and præ-Semitic "Pelasgian" race or were already mixed with Aryan Hellenic elements must remain for the present a moot question.

This seems to be the pith of Mr. Evans's arguments. He explores many byways of his subject in his exhaustive essay, but into these we have not the space to enter here, and it is easy to lose one's way in them, for they are a labyrinth as difficult to explore as Minôs's own! One point may be noticed, however; when Mr. Evans enters into comparisons of Mycenæan with Egyptian religious conceptions, we do not know that he will find Egyptologists in general inclined to agree with him. When, for instance, he compares the Mycenæan Pillar-cult with the Egyptian veneration of the well-known symbol of the Mendesian Osiris, the Ṭaṭ or Dad, often erroneously called "The Emblem of Stability," speaking of it as a "Pillar with its quadruple capital indicative of the four supports of heaven" (p. 146), he does not note that this explanation of the emblem is in the highest degree doubtful, for in all probability it is not a pillar at all, but an extremely ancient and traditionally conventionalised representation of the holiest relic of the god, the Backbone of Osiris. And if comparisons with Mycenæan heraldic designs are to be sought, the heraldic conceptions of the early Babylonians might more aptly be quoted than those of the Egyptians. Further, of Mycenæan influence on Egyptian art little trace can be found beyond the temporary adoption by the Egyptians of the false-necked vase (*Bügelkanne*); and of the remarkable evidence of this influence, which, according to Mr. Evans (p. 148), the monuments of Tell el-Amarna exhibit, nothing can be said, simply because it is in no way apparent. The naturalistic vigour of the artists of Åkhenåten's court was as purely Egyptian in its origin as was the cult of the *Åten* itself.

From the above remarks, however, it will be evident that in his monograph Mr. Evans has once again made a most notable contribution to our knowledge of Mycenæan culture, and that he has proved his main point there will be little doubt in the minds of those archæologists who are not bound by preconceived notions as to the origins of Greek civilisation. H. H.

ANCIENT MEDICINE AND BOTANY.

Magistri Salernitani nondum editi. Catalogo ragionato della Esposizione di Storia della Medicina, aperta in Torino nel 1898. By Piero Giacosa. Pp. xxxiv + 723. 8vo, with Atlas in folio. (Torino: Bocca, 1901.)

THIS fine work owes its origin to the "General Italian Exhibition," held at Turin in 1898. The author, Sig. Giacosa, suggested the formation, on that occasion, of a section for the history of medicine, in which should be collected documents illustrating that subject from the great libraries of Italy. A similar collection had been brought together at the International Medical Congress held at Rome in 1894, but, unfortunately, had been dispersed without being properly catalogued or described. It was therefore proposed also that on this occasion a complete descriptive catalogue should be prepared.

These propositions were favourably received by the Minister of Public Instruction and other authorities, with the result that, in response to invitations sent out, a large number of precious manuscripts, archives and other documents were sent in from various public libraries, forming probably the most remarkable collection of its kind ever brought together.

Most of the public libraries of Italy contributed to the exhibition, but there were certain exceptions. The absence of any contribution from the library of the Vatican is easily understood; but we regret to observe that nothing was sent from the splendid Laurentian library at Florence, which is particularly rich in works of this class.

The most remarkable part of the collection consisted of ancient medical manuscripts, dating from the ninth century onwards, many of them richly illustrated, and important in the history of art as well as in that of science. The text of many of these had never been printed, and the marvellous illustrations had remained entirely unknown except to those who were able to study them in the libraries where they are preserved. Before these treasures were again dispersed, Sig. Giacosa, assisted by eminent scholars, transcribed, and has here published, some very important inedited manuscripts, and reproduced specimens of the text by photography. In addition, some of the more remarkable pictorial illustrations which adorn the older codices have been also reproduced in the splendid atlas which accompanies the work.

The first part of the printed book consists of previously unpublished medical writings belonging to the school of Salerno, "Magistri Salernitani nondum editi." Salerno was the seat of the earliest medical school—indeed the earliest University—in Europe, which produced a medical literature of its own before the Arabian medical writers, with their versions of the Greek medical classics, occupied all the schools of Europe and formed the basis of European medicine in the Middle Ages. The study of the school of Salerno is most important in the history of medicine, and the texts published by Sig. Giacosa, which supplement in many ways the "Collectio Salernitana," edited by Henschel, Daremberg and de Renzi, nearly fifty years ago, form an important contribution to that study.

The second part of the book contains an admirable detailed description of the ancient MSS., more than one hundred in number, which were exhibited. This catalogue, containing numerous extracts with references to other MSS. and printed texts, forms, beside its immediate value, an excellent guide to the treasures of this kind preserved in Italian libraries.

It would be out of place here to enter on the interesting questions relating to the history of medicine which are raised in this volume, but we desire to call attention to the important bearings of some of these ancient works, and especially of the illustrations reproduced in the atlas, on the history of botany.

It is well known that a considerable number of works on medical botany, written in late Roman times, have come down to us and are still preserved in MS. in several European libraries. The most celebrated and probably the earliest is the MS. of Dioscorides, of the fifth century, now at Vienna, but originally brought from Naples, which is illustrated with a large number of coloured figures of plants. Another work, bearing the name of "Herbarium of Apuleius Platonicus," exists in many codices, and is always illustrated with the same series of figures, copied from one MS. to another. The ancient Anglo-Saxon version of this work, in the British Museum, with the same figures, has been printed in Mr. Cockayne's "Anglo-Saxon Leechdoms." There are others, which need not be mentioned here.

The text of these works has little botanical interest, being the work of mere servile compilers. But the illustrations have a peculiar and indeed unique value, and this *because* they are the work of copyists, who have transmitted to us, more or less accurately, a tradition of the way in which classical artists of the Roman period figured plants. The great MS. of Dioscorides is unique, or nearly so, and whether its figures were copied from still earlier figures we cannot say. But the earliest MSS. of Apuleius (ninth century) were probably copied from earlier works, and exhibit, therefore, a still earlier period in science and art.

These rich materials for a study of ancient botanical illustration have been most imperfectly explored, and have never been reproduced for the benefit of students in general. There is a printed edition of Apuleius issued by Philip de Lignamine at Rome about 1480, with rough copies of the figures in the original MS.; but the book is almost as rare as the manuscripts. The figures of the Vienna Dioscorides were copied on copper plates in the eighteenth century; but only two impressions are known to exist. A few were reproduced in Daubeny's "Roman Husbandry" and elsewhere, but they amount to very little. It would be a worthy, though costly, enterprise for some Government or academy to reproduce one of the old MSS., with its figures in their original colours.

We are therefore glad to see that Sig. Giacosa has copied in his atlas some of these ancient figures of plants. The chief characteristics of the school, viz. the diagrammatic representation of the plant with artificial symmetry, the disproportion of parts, the formal outline, and the decorative aim of the whole, can be well traced; while a comparison of figures of different dates shows the growth of conventionalism. Some realistic botanical figures of later schools form an instructive contrast.

As an example, we can only refer to the figures of one plant, the celebrated *Atropa mandragora* or mandrake, of which so many fables have been told. A comparison of the representations of this plant at different periods shows the gradual development and embellishment of the legend.

The legend of the mandragora, a formidable plant which caused the death of whoever pulled it up, so that a dog was employed in this fatal task, as told by Josephus and others, is well known. We find here, however, from a MS. of the ninth century, a fuller account than we have met with elsewhere, which it may be of interest to translate:—

"Mandragora is a plant which the poets call *anthropomercas* [sic], since it has a root shaped like a man. It is given in wine to those who wish to undergo a surgical operation safely, as when stupefied by it they feel no pain. When you come to it you will recognise it because it shines at night like a lamp. When you see its head you must cut round it with a knife lest it should escape. For such is its virtue that on the approach of an impure man it quickly flees before him. Therefore you dig round it with a knife, which must not touch the plant, and carefully remove the earth with an ivory spade. And when you see the hand and foot of the herb, tie round it a new cord and fasten the cord to the neck of a dog which has been kept fasting, and a little way off place a piece of bread so that the dog (trying to seize the bread) may pull up the herb. But if you do not wish to kill the dog, since the herb has such a divine power that it kills in an instant whoever pulls it up, proceed as follows. Make a snare of a long rod, and tie the cord which is fastened to the herb to the top of the rod, and bend it down; so that when the rod springs up by its own force it will pull up the herb mandragora."

This merciful substitute for the dog we have not found mentioned elsewhere.

All the pictures of the mandrake accordingly show the dog and the cord, sometimes a spectator, stopping his ears, lest (according to another part of the story) he should hear the shriek uttered by the herb when pulled up, which it was death to hear. In some, presumably the older figures, the herb is merely a forked tap-root with arms, the extremities ending in fibres, and surmounted by a tuft of leaves. In later figures the tuft is replaced by a well-formed human head and the fibres by distinct fingers and toes.

There are other figures of plants which, without possessing the romantic interest of the mandrake, are well worthy of study, and furnish interesting, though difficult, problems in identification. Some old botanical glossaries are also worth attention.

We have quoted enough to show the botanical interest of Signor Giacosa's beautiful work. It is an important contribution to the history of science, and should find a place in all the greater botanical as well as medical libraries. J. F. P.

THE ANDES OF PATAGONIA.

Les Andes de Patagonie. Par L. Gallois. Pp. 28 + plates. (Paris: Librairie Armand Colin, 1901.)

THIS brochure treats almost entirely of the orography of Patagonia in its relation to the boundary-line question between the Argentine Republic and Chile, which is now *sub judice*, having been submitted to the arbitration of the English Government. The author claims that his "only object in this study is to assist in making better known one of the most curious regions of the globe";

but it is easy to see which side of the controversy he would espouse if he felt himself free to give his opinion.

His brochure is richly embellished by numerous beautiful plates of mountain chains, scenery around the lake districts and along the Andean foothills, taken from the Argentine "case," as presented to the Arbitrator, in five large folio volumes. He also reproduces several Argentine Government maps on a reduced scale.

M. Gallois sets forth the salient features of the various treaties and protocols which have, during a score of years, resulted from this question, and he justly regrets that "La formule que les diplomates adoptèrent fut donc tout simplement la formule traditionelle." "S'il y avait un pays au monde où les vieilles formules dussent être avec soin évitées, c'était la Patagonie." In this opinion he is not alone, for every student of South American politics and geography must lament the interminable blunders made by diplomatists and lawyers when they rely upon their own language to determine frontier lines instead of submitting their description to scientific experts.

M. Gallois especially criticises the ignorance of the framers of the treaties regarding rivers which eat back until they have established their determined vertical curve of equilibrium. Herein is the crux of the whole dispute between the Argentine Republic and Chile. The former claims that the boundary line should be traced along the highest crests and peaks of the main Andean chain; and the latter claims that the treaties demand the tracing of the line along the continental *divortia aquarum*. But some of the rivers which flow into the Pacific Ocean have sawed back through the Cordillera and now have their sources upon the Patagonian plateau to the east of the Andean main chain. Thus the rival claims are in direct conflict. Many cases of this tendency of rivers may be found in almost every country in South America, and Colonel Church, in his "Physical Geography of South America," has given us numerous instances of it, especially in Ecuador, Perú, and Bolivia.

The brochure has a laconic but excellent description of Patagonia in a few pages, and gives due credit for information to Chilian as well as Argentine explorers. A long line of cliffs borders the Atlantic coast, interrupted at rare intervals by great valleys which open on to the sea. The surface of the immense Patagonian plateau rises gradually towards the west up to the vicinity of the Cordillera. Here and there a depression is filled with saline waters, and, especially towards the south, the country is covered with immense sheets of basaltic lava. Deep valleys, too immense for the existing streams of water, cut the plateau in certain parts and have a labyrinth of affluent cañons.

"The aspect rapidly changes along the approaches to the Cordillera. . . . It is a broken region, often mountainous, rich in prairies; rich, above all, in sheets of water, the smallest of which equals the area of our great European lakes. A privileged country, where the climate is free from extremes, where moisture is sufficient, where forests, easily penetrated, adorn the mountain sides. It is there that Argentine colonisation has been developed, and also *there* are the disputed territories.

"More to the west, but without the transition being suddenly established, commences what we call, without prejudging anything, the main chain.

"The Cordillera drops suddenly to the sea from 42° south latitude. Up to 47°, it dominates a long submerged depression which visibly continues the interior plain of Chile. . . . Further to the south the outline is less defined."

He notes the marked resemblance of this Pacific coast to that of Alaska and Norway—scored and penetrated by fjords and channels cutting the coast-line into islands and presenting numerous glaciers. Many rivers find their way to the Pacific Ocean through deeply carved valleys in the Cordillera, but so violent and broken in their course that none of them are navigable except for a very short distance from the sea.

Such is the outline that M. Gallois gives of Patagonia, and it enables the reader to acquire a very fair general knowledge of the orography and topography of the country without studying the voluminous works which have been prepared for the umpires in the boundary-line dispute. It is to the credit of M. Gallois that, however difficult, he has found it possible to preserve an impartial attitude in his instructive and ably-written brochure.

G. E. C.

WIRELESS TELEGRAPHY.

Wireless Telegraphy. By G. W. de Tunzelmann. Pp. iv + 104. (London: Office of *Knowledge*, 1901.) Price 1*s*. 6*d*.

MR. DE TUNZELMANN, in writing a popular account of wireless telegraphy, has attempted the double task of describing its historical development and of giving an account, which shall be intelligible to the lay reader, of the fundamental principles of the subject. The descriptive parts are based mainly on the papers which have been read by Mr. Marconi, and explain in an interesting manner free from superfluous detail the system which he has worked out. It is to be regretted that the work of other experimenters is hardly adequately recognised; Prof. Slaby, for example, deserves more than the half dozen lines allotted to him. Moreover, such information as is given is easily accessible in Mr. Marconi's published papers, whereas a careful comparison of the systems devised by the various workers would be a valuable addition to the literature of the subject.

In the theoretical portions of the book the author has largely drawn his inspiration from Prof. Lodge's "Modern Views of Electricity." Without wishing in any way to disparage Mr. de Tunzelmann's explanations, we doubt whether they would be intelligible to readers who, as he says in the preface, "know little or nothing of electrical theory." A clear comprehension of the constitution of the ether and the mechanism of ether waves is not to be obtained without serving a long and severe apprenticeship in the study of physical science. Yet it is supposed that the lay mind, because it is attracted by the wonderful results of wireless telegraphy, is capable of appreciating the intricate physical theories with which the subject is bound up. It is as though a man should be expected to be able to weigh the merits of the electrolytic dissociation theory because he admires the electroplate upon his dinner-table. We doubt whether any useful end is served by such "popular" expositions, which can only lead to the spread of pseudo-scientific ideas based on ill-digested theories. It must be admitted, however, that on the whole Mr. de Tunzelmann has treated the subject broadly and clearly, and his explanations should at any rate be of considerable service to the student.

ZOOLOGICAL PROBLEMS STUDIED BY A PSYCHOLOGIST, PSYCHOLOGICAL PROBLEMS STUDIED BY A ZOOLOGIST.

Animal Behaviour. By C. Lloyd Morgan, F.R.S. Pp. viii + 344. (London: Arnold, 1900.) Price 10*s.* 6*d.*

THIS interesting and highly suggestive work grew out of an attempt to revise the author's "Animal Life and Intelligence." It was found that "the amended treatment would not fall conveniently under the previous scheme of arrangement." The subject is divided into seven sections, dealt with in as many chapters, the first concerned with "Organic Behaviour," the second "Consciousness," the third "Instinctive Behaviour," the fourth "Intelligent Behaviour," the fifth "Social Behaviour," the sixth "Feelings and Emotions," the seventh "Evolution of Animal Behaviour." The illustrations are numbered 1 to 26; but some of them contain several figures. Part of the work is coarse and unsightly, although clear (*e.g.* Fig. 13); on the other hand, some of the process blocks are quite successful, especially those which reproduce Mr. Charles Whymper's three drawings (Figs. 4, 5, 15). The book is well and clearly printed, and there are very few slips or misprints.

The first chapter of the work opens with an introductory section on behaviour in general, followed by an account of the more fundamental types of behaviour, viz. of cells and cell-aggregates, of plants and of reflex action, which latter is held to involve the existence of a differentiated nervous system. The chapter concludes with a section upon the evolution of consciousness, while the five succeeding chapters similarly include discussions upon the evolution, respectively, of consciousness, instinctive, intelligent, social and emotional behaviour. The last chapter is confined to the consideration of the evolution of animal behaviour. The principles which the author lays down for his guidance in the discussion of animal behaviour are the attempts to realise, in every case,

"first, the nature of the animal under consideration; secondly, the conditions under which it is placed; thirdly, the manner in which the response is called forth by the circumstances; and fourthly, how far the behaviour adequately meets the essential conditions of the situation."

A rigid adherence to these wise principles, perhaps more than anything else, leads to a sense of confidence and security as we are guided through the intricacies of this most complex subject. Our gratitude is all the more real because of the difficulty and confusion which have been gratuitously introduced into the study of animal behaviour on account of the unfortunate conviction held by nearly every owner of a domestic pet that he, or even more frequently she, is intimately acquainted with the workings of its mind, and because of the unfortunate zeal with which hasty conclusions are spread abroad. May every lover of dog stories be induced to read the observations and conclusions on dog-behaviour (p. 141 *et sqq.*), and learn caution and restraint in interpretation. And caution is not needed less, but more, when the subjects of observation are farther removed from us in the zoological system, and combine far more wonderful instincts with a psychology more difficult to penetrate because far more remote and foreign to us. Maurice Maeterlinck's charmingly written book on the bee would have been more trustworthy if its author had received the advantage of Prof. Lloyd Morgan's friendly guidance in "Animal Behaviour" and his other kindred works. Many poetically expressed motives which are believed to bring about the wonderful instincts of the bees, and thoughts which are supposed to guide them, would thus have been advantageously omitted.

In speaking of the corporate behaviour of the cell-units of the higher animals it is well pointed out that the periods of apparent rest are in reality the periods of work during which are elaborated and stored up the unstable substances in preparation for the time of action;

"just as the brilliant display of intellectual activity in a great orator is the result of the silent work of a lifetime, so is the physical manifestation of muscular power the result of the silent preparatory work of the muscle-cells."

In explaining this apparently wasteful and roundabout process the author points out that

"only thus could the organs be enabled to act under the influence of stimuli and afford examples of corporate behaviour. They are like charged batteries ready to discharge under the influence of the slightest organic touch" (p. 23).

The adaptive behaviour of plants is illustrated by a few of the most remarkable examples, such as the fertilisation of *Vallisneria* and *Catasetum*, and we are led to the safe conclusion that the behaviour, beautiful and effective as it is, "does not afford any indication of the guidance of consciousness." Nowhere among plants do we meet with

"so much as a hint of that profiting by individual experience which is the criterion of the effective presence of conscious guidance and control" (p. 31).

With the same wise caution the terms "discrimination" and "perception" are abandoned in favour of "differential reaction" in speaking of the movements of the tentacles of the sun-dew and of some of the lower animals. Thus all possibility of confusion with conscious choice is deliberately excluded.

In the brief section on the evolution of organic behaviour the author provisionally rejects the hypothesis of the hereditary transmission of acquired characters. He follows Osborn's convenient restriction of the term *modification* to the changes wrought by use or environment, and *variation* to the inherent differences which are due to the germ-cell. The distinction between these two classes of characters is carefully drawn and clearly illustrated, although the author omits to point out with sufficient clearness that the favourable *modification* is dependent no less than the favourable *variation* upon natural selection. The power of the organism to respond adaptively to environmental stimuli is probably an even higher effort of natural selection than that put forth in the production of some favourable inherent character which comes forth ready-made in the developing individual

before any occasion for its use has arisen. The relation of body-cell to germ-cell in the struggle for existence and in evolution is clearly explained in an admirable comparison with the sterile and fertile individuals of the hive. By this means two complex and difficult subjects which have puzzled many a student of evolution are together rendered easy of comprehension.

The supposed cases of the instinctive hereditary fear of the dog by the kitten, the hawk by the young turkey, &c., are examined with much care in the chapter on consciousness. This examination and the result of the author's observations, together with those of Dr. Thorndike, Mr. W. H. Hudson and Mr. Frank Finn, lead to the conclusion that an inherited timidity ready to find instant expression at any unusual sight or sound has been erroneously interpreted as the hereditary fear of certain special enemies.

The stages of the evolution of consciousness are summed up in the statement that "in the first stage we have consciousness as accompaniment; in the second, consciousness as guide; in the third, consciousness as judge."

The term *instinct* is wisely limited to behaviour which is independent of experience. Acts which, at first voluntary, have become mechanical in the course of an individual life are regarded as *acquired habits*, the popular as well as the occasional scientific use of the term *instinctive* for this purpose being rejected. The definiteness of instinct is by no means held to imply that it is rigidly the same in all individuals of a species. Individual variation, bringing instinct under the sway of natural selection, is freely admitted, as it was by both Darwin and Wallace in their joint essay in 1858. The author's position in this respect is a return to the sound principles first laid down by the great originators of the theory of natural selection and a rejection of the attempt to improve upon these principles by a widely different, and for a time very popular, conception of instinct as due to the hereditary transmission of the results of intelligent learning, practice and habit, an interpretation which received a fatal blow in Weismann's critical attack upon the evidence in favour of the transmission of acquired characters in general. The whole question is discussed in an extremely fair and convincing manner in the section on the evolution of instinct (pp. 106–116).

The full definition of instinct which is here adopted closely follows Dr. and Mrs. Peckham's summary of the conclusions to which they were led by their deeply interesting study of the solitary wasps. Instinctive behaviour comprises

"those complex groups of coordinated acts which are, on their first occurrence, independent of experience; which tend to the well-being of the individual and the preservation of the race; which are due to the co-operation of external and internal stimuli; which are similarly performed by all members of the same more or less restricted group of animals; but which are subject to variation, and to subsequent modification under the guidance of experience" (p. 71).

This is a definition which it is believed that Darwinian naturalists in general will be prepared to accept, as well as its application, *e.g.*, to the flight of birds where it is inferred

"that instinct provides a general ground plan of behaviour which intelligent acquisition, by enforcing here and checking there, perfects and guides to finer issues" (p. 88).

The whole section upon the instinctive behaviour of young birds (pp. 84–98) abounds in original observations carefully carried out and interpreted with caution and judgment; they lead the author to the conclusion that experience is not hereditary.

The chapter on intelligent behaviour opens with the discussion of simple examples which lead to the statements that

"whereas instinctive behaviour is prior to individual experience, intelligent behaviour is the outcome and product of such experience,"

and again,

"instinct depends on how the nervous system is built through heredity; while intelligence depends upon how the nervous system is developed through use."

It may be doubted whether these sound and excellently expressed principles are applied with sufficient rigidity to the wonderful behaviour of insects. Thus Dr. and Mrs. Peckham's observation of the use of a stone by the solitary wasp *Ammophila urnaria* to beat down the earth with which she was filling up the entrance of her excavation is spoken of as "intelligent procedure," and is referred to even more strongly in the words, "here we have intelligent behaviour rising to a level to which some would apply the term rational." And yet it is in every way probable, in fact almost certain, that the whole behaviour of the *Ammophila* depended upon the manner in which "the nervous system was built through heredity," and that if the American naturalists had been fortunate enough to witness the first performance of the wasp it would have been found to be as perfect as any at any later period in its life. It may be questioned whether the use of the word "tool" is to be justified in speaking of the employment of the fragment of stone. A "tool" is not any object which may be used for a purpose, but an object fashioned for the purpose it is made to serve—a criticism which was suggested to the present writer by Prof. E. Ray Lankester in a conversation about this very observation. The use of decayed wood in the construction of combs by many wasps is probably a more complex piece of behaviour and more difficult to understand as a pure instinct than the behaviour of the *Ammophila*, and yet in this case the interpretation is certain. The present writer has seen the worker of a species of *Vespa* freshly emerged from the pupa, and the sole perfect insect upon the young comb (the queen mother having been previously killed) immediately seize upon the broken material of the comb and begin accurately and with exact precision to build up the thin and delicate sides of injured cells containing the living larvæ. We may feel confident from this fact that the worker possesses a nervous system which impels it from the first to seek the right material and do the highly complex work and enables it, without intelligence, at the outset to make use of wood of the right texture, dryness, &c. The use of stones, &c., for closing the mouth of the burrow is probably as ingrained in the nervous system of *Ammophila* as the use of wood in making cells is in the genus *Vespa*. In addition to the observation of Dr. and Mrs. Peckham, we

have that of Dr. S. W. Williston upon another species, *A. yarrowi*, and still later, in the summer of 1899, the present writer and three others observed the same thing in a large species of *Ammophila* (propably *A. sabulosa*) at St. Helens, Isle of Wight. The latter observation followed very closely the account given by Dr. Williston. After the wasp had placed the larva in the burrow and, as was subsequently ascertained, laid an egg upon it, she seized, not a pebble, as in Dr. Williston's case, but a piece of peat or fibrous root, and forced it into the hole. The object of this was undoubtedly to act as a plug and prevent the earth from falling into the cell where the larva lay. Then earth was thrown upon the plug and after this an angular fragment of brick, which needed some effort to force into the tube; then more earth and a final raking of the surface and scattering of twigs, &c., which obliterated all traces of disturbance. The piece of brick seemed to be in the nature of a burglar-proof door rather than a smoothing or pounding apparatus, in this particular instance. The soil was dry and sandy and perhaps did not need such special methods. At a previous stage the wasp acted as if with intelligence in dragging the larva into the burrow and then very rapidly out again in order to enlarge it still further. But this action is also in all probability the outcome of a nervous system built through heredity which impels the wasp to bury the larva in such a manner as to provide food and space for the wasp's growing offspring. The instinct requires a trial for its complete fulfilment. The evidence required to prove intelligent behaviour would be the observation that the wasp excavated more accurately and needed fewer trials with her prey, as, in the course of her life, "the nervous system developed through use." But any such evidence is as unlikely as that the other wasps should require experience to build their combs with exactness. We are dealing, in insects, with animals which commonly require to do various elaborate acts each but once in a lifetime, and thus always "prior to individual experience." The behaviour which leads to the production of an elaborate cocoon or the burial of a larva in its earthen cell is clearly instinctive, and the most convincing evidence is required in order to prove that certain insects which perform the same elaborate act many times in their lives are guided by anything except the compulsion of a "nervous system built through heredity."

The experiments and conclusions upon the intelligent behaviour of the higher vertebrates are most convincing. They are introduced by a clear statement of the essential nature of rational behaviour and the wide difference which separates it from intelligent behaviour. The attempt made by the author and Dr. Thorndike (pp. 153, 154) to set forth the mental condition of one of the higher animals is deeply interesting. Dr. Thorndike's "animal consciousness" sometimes felt during swimming will appeal to many as a very real experience, when

"one feels the water, the sky, the birds above, but with no thoughts about them or memories of how they looked at other times, or æsthetic judgments about their beauty; one feels no ideas about what movements he will make, but feels himself make them, feels his body throughout. Self-consciousness dies away. Social consciousness dies away. The meanings, and values, and connections of things die away. One feels sense-impressions, has impulses, feels the movements he makes; that is all."

In the discussion upon the evolution of intelligent behaviour a most interesting and ingenious experiment made by the author is recorded. The close resemblance between specially protected species was explained by Fritz Müller in 1879 by the hypothesis that life was saved during the education of young and inexperienced enemies when the number of colours and patterns was few. Thus one appearance under this hypothesis may serve as a warning for many species, and it is not necessary for enemies to test more than a certain proportion of the species in order henceforth to avoid the whole. Prof. Lloyd Morgan made the following experiment in the attempt to discover whether the behaviour of a possible enemy is such as the Müllerian hypothesis assumes.

"Strips of orange and black paper were pasted beneath glass slips, and on them meal moistened with quinine was placed. On other plain slips meal moistened with water was placed. The young birds [chicks] soon learnt to avoid the bitter meal, and then would not touch plain meal if it were offered on the banded slip. And these birds, save in two instances, refused to touch cinnabar caterpillars [with black and orange bands], which were new to their experience. They did not, like other birds, have to learn by particular trials that these caterpillars are unpleasant. Their experience had already been gained through the banded glass slips; or so it seemed. I have also found that young birds who had learnt to avoid cinnabar caterpillars left wasps untouched. Such observations must be repeated and extended. But they seem to show that one aspect of the Müllerian theory is not without some facts in support of it; and, so far as they go, they afford evidence that black and orange banding, irrespective of particular form, may constitute a guiding generic feature in the conscious situation."

This evidence is of especial interest to the student of mimicry, particularly to the present writer, who ventured to suggest (*Proc.* Zool. Soc., 1887, p. 235) a Müllerian association between the cinnabar larva and the wasp.

In the account of "Müllerian mimicry" (p. 164) the hasty reader might infer that Dr. Fritz Müller had depended on Mr. Frank Finn's observations upon birds, observations made after Müller's death and about twenty years after the publication of his hypothesis. A reference to the publication, from which a sentence is quoted, would prevent any possible misconception.

Want of space prevents any discussion of the remaining chapters, which are full of interest. Prof. Groos' theory of animal play as a preparation for the serious business of life is explained in a luminous manner (pp. 248 *et sqq.*), so that the reader will gain a perfectly clear idea of one of the most important of recent contributions to Darwinian theory. Dr. Louis Robinson published an outline of this idea the year before Prof. Groos' work appeared. Thus in the Reports of the British Association for 1894, p. 778, the abstract of Dr. Robinson's paper to Section H contains these words:—

"It is found that in young apes, puppies, and other like animals, the most ticklish regions correspond to the most vulnerable spots in a fight. In the mock fights of immaturity, skill in defending these spots is attained."

And Prof. Lloyd Morgan himself had written still earlier on the same subject (*Atalanta*, January 1889).

The discussion of animal courtship and its psychological analysis constitute one of the most interesting parts of the work. The author's conclusions will, it is believed, be fully accepted by those who follow the Darwinian theory of sexual selection. The more exuberant phraseology of previous writers on the same subject was probably never intended to convey anything very different from the conduct and climax of courtship as here described. But it has required the assistance of one trained both as psychologist and as zoologist to expound the subject so that misapprehension is well-nigh impossible. The author's twofold capacity in dealing with subjects which require to be looked at from very different points of view, as expressed in the title of this review, renders, not only the discussion of courtship, but the whole work, of great value to students in two very different yet closely related fields of knowledge.

E. B. P.

CELLULOSE.

Researches on Cellulose from 1895–1900. By Cross and Bevan. Pp. vii + 180. (London: Longmans, Green and Co.) Price 6*s.* net.

VEGETABLE substances or products of vegetable origin have always had a peculiar fascination to chemists, not only because of the light which may be thrown on general chemical science, should methods of synthesis be discovered, but often because, as was the case with alizarin and more recently with indigo, huge industrial applications may be the outcome of this branch of research. Further, researches are often conducted with the hope that we may be enabled to reveal some of the hidden secrets of nature, as, for example, how the elements which are assimilated by plants in the form of the simplest of compounds become ultimately converted into some of the most complex combinations known to chemists.

In "Researches on Cellulose," by Cross and Bevan, we are dealing with a class of substances which may be said to form the structural basis of all natural organic substances. A very large amount of research has been carried out with the object of ascertaining the molecular configuration of the celluloses, but it cannot be said, up to the present, to have thrown very much light upon the ultimate structure of these substances. If the researches on cellulose have not been very fruitful in this direction, they have, on the other hand, been of enormous industrial importance. A very much larger number of industries are concerned with "cellulose" in one form or another than those who have not studied the subject are probably aware. We have only to think of the colossal scale upon which paper is manufactured and the employment of nitrocelluloses in the manufacture of smokeless powder to realise the far-reaching applications of cellulose.

The authors state in their preface that the present volume is intended as a supplement to the work which they published six years ago. The book is more or less in the form of abstracts of researches which have been published since 1895, but it also contains results of the authors' own investigations which have not previously been recorded. The chemistry of cellulose has attracted considerable attention abroad, but in England, with a few exceptions, it has been almost neglected. Messrs. Cross and Bevan call attention to this neglect, and remark that:—

"To the matter of the present volume, excluding our own investigations, there are but *two* contributions from English laboratories. We invite the younger generation of chemists to measure the probability of finding a working career in connection with the cellulose industry."

Considering the enormous importance, the vast extent and the almost unlimited possibilities of the cellulose industry, we trust that this invitation will meet with a hearty response. It is remarkable that in text-books on chemistry, with the exception of technical works—which in this country are few and far between—the subject of cellulose takes a very back-seat. But perhaps we can hardly blame the authors of such works, whose intention, generally speaking, is to teach the theory of organic chemistry. When very little is known about the theory of the subject, it is not unnatural that very little should be said about it.

The book commences with a general introduction, in which the authors reply to some of the criticisms of their previous work. They then explain in detail the plan of the book, and consider the following classification to be the most natural.

"Cellulose is in the first instance a *structure*, and the anatomical relationships supply a certain basis of classification. Next, it is known to us and is defined by the negative characteristics of resistance to hydrolytic actions and oxidations. These are dealt with in order of their intensity. Next we have the more positive definition by ultimate products of hydrolysis, so far as they are known, which discloses more particularly the presence of a greater or less proportion of furfural-yielding groups."

Until more definite knowledge of the ultimate structure of the various celluloses is known, this method of classification seems to be about the best.

The section on cellulose esters is extremely good, the paragraphs on the cellulose benzoates, which the authors have prepared by first treating fibrous cellulose (cotton) with a 10 per cent. solution of caustic soda and then with benzoyl chloride, being exceptionally interesting. It is rather interesting to note, by the way, that the dibenzoate is devoid of all structure, and is therefore readily recognised from the fibrous monobenzoate.

Under cellulose acetates the authors correct the statement made in their previous work that "on boiling cotton with acetic anhydride and sodium acetate, no reaction occurs." At the boiling point of the anhydride an ester is obtained, although without any apparent structural alteration of the fibre. Under esters is also included inorganic esters—the nitro-esters, which are of such importance in the manufacture of cordite, ballistite, "smokeless powders," &c.

The articles on *lustra-cellulose* or artificial silk will interest many, but the authors protest against the term artificial silk, and suggest that the term "*lustra-cellulose*" should be employed. Considering the manner in which the term "artificial" is so often misused, we quite agree. Inform the public that an article is artificial and they at once brand it as "false" or as a "substitute." In the

present case, lustra-cellulose is not silk at all. Why, therefore, call it silk? Messrs. Cross and Bevan likewise correct the oft-repeated statement that lustra-cellulose is highly inflammable, and point out that "Lehner" silk, which has been denitrated, contains only 0·19 per cent. of nitrogen.

There are many other sections in the book which we should like to dwell upon, but space forbids. We would only draw attention to the articles on constitution, furfuroids and industrial developments, all of which are of great interest.

The book before us is to a certain extent disjointed, but we have already stated that it consists largely of abstracts, therefore it is hardly to be expected that the authors could construct a connected narrative. In their anxiety not to *pad*, the authors have, at times, made the text almost too bare. For this reason it is sometimes hardly as clear as one could wish. This, however, is only a minor blemish. Messrs. Cross and Bevan are experts in this branch of chemistry, and have presented us with a book which is replete with important matter. It is not a book for the tyro, but we sincerely trust that it will be widely read by chemists, and we believe that research work on cellulose will be thereby greatly stimulated.

F. MOLLWO PERKIN.

OUR BOOK SHELF.

Irish Topographical Botany. By R. L. Praeger. Pp. clxxxviii + 410. (Dublin: Hodges, 1901.)

Practical Text-book of Plant Physiology. By D. T. Macdougal, Ph.D. Pp. xiv + 352. (New York and London: Longmans, Green and Co., 1901.) Price 7*s*. 6*d*. net.

THE botanical survey of a country demands a good deal from the men who undertake it, and one source of confusion now apparent in the many and various attempts being made in many and various parts of the world is the different ideals set up by different workers as to what constitutes a botanical survey. The purpose of Mr. Praeger's well-printed but somewhat heavy book is to give records of the county distribution of plants in Ireland, and the task—probably a thankless one in proportion to the labour it must have cost—seems well done. To our thinking, however, the book is only rescued from being a very dry and bulky reference list by the attempt, in Section ii. of the introduction, to sketch in outline the botanical features of Ireland in terms of plant communities.

It must be added, however, that the list appears to be very complete and is accompanied by six excellent maps, and there can be no doubt that the work will be indispensable to the reference library of the systematic botanist.

Dr. Macdougal has written an interesting and, in many ways, an excellent text-book. We have often wondered why plant physiology should so often be treated from the point of view which emphasises the obscure relations between structure and function involved in the phenomena of life and which almost ignores the many side-issues bearing on the practice of plant-culture, and it is a pleasure to see a work in which these latter are kept in view.

Many of the experiments are neat and well chosen, and the most striking are often the simplest—*e.g.* that of Molisch for demonstrating the hydrotropism of roots (Fig. 28), or that selected for showing the swelling of seeds on imbibition (Fig. 84).

Many readers would probably have wished for fuller discussion of theoretical points. The short statement on p. 215, for instance, as to the ascent of water in plants, is meagre if not misleading. The sentence on p. 8 hardly does justice to Czapek and Pfeffer's clever work on the geotropic region of the root-tip, or to Darwin's beautiful proof that the tips of *Setaria* seedlings are alone sensitive to the heliotropic stimulus, while the wholesale acceptance of Nemec's conducting fibrillæ probably needs further justification.

As sometimes happens with American books, the English reader may be startled, if not puzzled, by some of the expressions—*e.g.* "the substances illy affected" (p. 57) and "A second experiment, exploited by Pfeffer and extended by Czapek" (p. 78) seem to need explanation.

In spite of faults, however, the book may be welcomed as a useful one.

Botany, an Elementary Text for Schools. By C. H. Bailey. Pp. xiv+355. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.) Price 6*s*.

THIS volume, like all Prof. Bailey's works, bears the stamp of originality, and in many respects forms an excellent model of what a school book on botany ought to be. Naturally the examples chosen for study are such as can be easily procured in America, but teachers at home might readily learn much from the author.

The details of plant-structures are introduced in a way calculated to excite the interest and attention of the learner, and the very numerous illustrations are directed to the same end. They are excellently chosen and admirably executed. The portion of the book which is devoted to an account of the minute structure of the tissues strikes us as the weakest part of the whole, and also as perhaps the least useful, having regard to the needs of beginners in the study of plants. The concluding pages give directions for forming collections of plants and for determining the species which are likely to be commonly met with.

Not the least valuable of the lessons to be drawn from Prof. Bailey's book are to be found in the preface, in which much sound advice is given as to the kind of work most suited to the needs of school children. After all, it is the training which is the thing of real value—the development of the faculties of observation and of drawing right inferences from observed facts.

(1) *Curso Elemental de Física Moderna*; (2) *Elementos de Física Moderna*. By Dr. R. Pedro Marcolain San Juan. (1) Pp. 804, with 894 woodcuts; (2) pp. 492, with 608 woodcuts. (Zaragoza: Emilio Casañal, 1900.)

THESE are two treatises on descriptive physics, of which the second book is merely an abridged edition of the first. Each is divided into three parts. The first deals with mechanics, including hydromechanics and acoustics; the second with radiology, including heat as well as light; and the third with electricity, being subdivided under the headings of electrostatics, electrodynamics and electrotechnics. In speaking of the subject-matter as descriptive physics, in contradistinction to mathematical or experimental physics, we mean to imply that the books belong to the class of popular treatises containing a general description of the properties of matter suitable for ordinary readers, and illustrated by pictures of steam engines, barometers, siphons, Atwood's machines, pumps, batteries, water boiled by cold, electric telegraphs and all that sort of thing. It is rather amusing to find in the chapter on general dynamics in the larger volume, not only an account of the *mechanism* of the Funicular Railway up Vesuvius, but also a description of the crater and of the panorama from the summit.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Effect of a Magnetic Field on Spectra of Helium and Mercury.

THE Department of Natural Philosophy in this University has recently acquired, through a fund provided by the liberality of the Bellahouston Trustees of Glasgow, a fine echelon grating of twenty-six plates made by Hilger, London. The instrument has excellent definition, and its great power enables it to show Zeeman effects with moderate magnetic fields. In conjunction with a new electromagnet which has been constructed for the Department by Messrs. Mavor and Coulson from the same fund, we have been able to make some preliminary observations which may be of interest to readers of NATURE. The magnet and spectroscope were shown at the recent British Association meeting, when some account of the power of the set of instruments was given. The magnet when excited by a current of only five or six amperes gave a field of about 50,000 C.G.S., and was found capable of giving still higher intensities.

We have examined the Zeeman effect for the yellow helium line D_3. The line, as is well known, is a doublet; the wave-length of the brighter component is 5875·883 Ångström units, that of the fainter 5876·206 units. The lines broaden with increasing field, till at 6500 C.G.S. the fainter is a distinct doublet. As the field is increased the components of the doublet separate farther, but we have not observed any further splitting. The brighter of the D_3 pair is not distinctly resolved till the field is 9100 C.G.S., when it appears as a triplet; it remains so in higher fields.

In a very high field, the strength of which was not observed, the green (5460) line of mercury was resolved into nine components.

We have not so far come across any previous statement of these results, though of course they may be well known to observers of magneto-optic phenomena. We are now arranging for careful measurement by photography and otherwise of displacements produced by fields of known strength, in order if possible to answer some of the outstanding questions on the subject.

ANDREW GRAY.
WALTER STEWART.

Physical Laboratory, The University, Glasgow, November 15.

Observations of Leonid Meteors.

OBSERVATIONS were made of the Leonid meteors with the intention of determining the intensity and epoch of the shower. Unfortunately, however, owing to cloudy weather on November 13 and 14, observations were restricted to the three following nights. The annexed table gives the total number of meteors observed each night:—

	Extreme limits of the period during which observations were made.	Total duration of watches.	Number observed.	
			Leonids.	Other Meteors.
	h. m. h. m.	h.	h.	m.
Nov. 14	13 0–17 50	$4\frac{3}{4}$	106	94
„ 15	11 45–17 35	5	89	89
„ 16	12 15–14 15	2	7	29
Total		$11\frac{3}{4}$	202	212

During the whole of the time of observation the conditions were practically perfect, save that on the 16th there was a haze over the lower part of the sky.

The Leonids were rather less numerous during the earlier watches on the 15th than later on, but otherwise no well-defined variation in their number was noticed during the period of observation. The curious manner in which they came in groups was, however, very marked. One rather striking example of it occurred on the 15th, when three sprang out almost simultaneously, followed by another about four seconds later, and this at a time when the hourly rate was only about twenty. Their brightness varied in most cases between the 1·5 and the 3·5 magnitude, which was considerably above the mean magnitude of the other meteors. Only two meteors brighter than the first magnitude were observed, both of which were Leonids. The latter of these, which was seen on the 16th at 13h. 58m., commenced its path at 11 Monocerotis, and passing directly over μ Leporis, disappeared three degrees beyond. It left a train of irregular width, part of which remained visible for about six seconds.

No very systematic attempt was made to determine the radiant, but as far as could be judged it was at 150° + 23°, and was sharply defined at any rate for much the larger proportion of the meteors. It is, perhaps, worth mentioning that several meteors very similar to Leonids in appearance were observed to radiate from a point a little above the sickle, and it is possible that some of these, or some from other radiants, may have been recorded as Leonids. Doubtful meteors were in all cases counted with the class to which it seemed most likely they belonged.

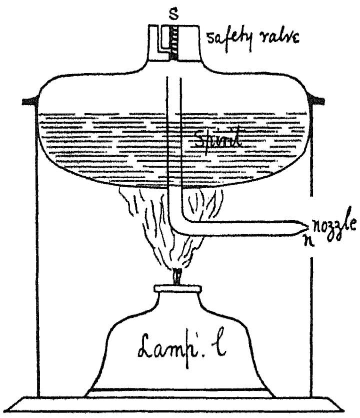
Comparing these observations with those which I made last year I should say that the shower was appreciably more intense this year on the 14th and 16th, and much more intense on the 15th. I should remark, however, that last year I recorded the maximum as occurring during the latter part of the night of the 13th, while on this occasion I have no observations for that period. For the sake of comparison, however, I may say that I consider the shower of the 14th this year about equal in intensity to that of the 13th last year. E. C. WILLIS.

Southwell Lodge, Norwich, November 18.

A Curious Flame.

FOR some time past I have shown as a lecture experiment a vibratory flame which illustrates in a striking manner phenomena similar to those to which Mr. Garbutt directs attention in your issue of October 31.

The flame (which is of the "washed-out" type) is produced by means of a common form of spirit blast-lamp, the construction of which will be sufficiently evident from the accompanying figure. If after using the blast which issues from the nozzle N,



the small subsidiary lamp L be removed from the position shown in the sketch and then placed from three to four inches in front of the nozzle, a blue flame cone will in a second or two dart back from the flame of L to N. The lamp L may now be completely removed, and the flame cone will continue—adder tongue like—to dart back and forth between N and a point three to four inches distant for hours together.

A baffle (in the form, say, of a glass tube or a knitting-needle) held in the track of the vibrating flame at a distance from N less than its normal traverse, will not permit the flame to pass it. But clearly the baffle cannot in this case *permanently* tether the flame cone. It merely curtails the amplitude of vibration without affecting materially its frequency.

If the safety-valve S be replaced by a cork carrying a U-tube the bend of which contains water, there is a rise and fall of water-level synchronising with the vibratory motion of the flame cone. The apparatus thus becomes a heat-engine producing reciprocating motion in an ideally simple manner.

If a small compound strip of ferrotype plate and zinc foil be used to baffle the flow of vapour from N, the strip curls up appreciably every time the tongue of flame licks it, uncurling again in the intervals. By including this strip in an incomplete electric bell circuit the bell may be caused to sound in synchronism with the vibrations of the flame.

Blackheath, November 11. DOUGLAS CARNEGIE.

AN ATTEMPT TO ASCERTAIN THE DATE OF THE ORIGINAL CONSTRUCTION OF STONEHENGE FROM ITS ORIENTATION.[1]

THIS investigation was undertaken in the spring of the present year, as a sequel to analogous work in Egypt and Greece, with a view to determine whether the orientation theory could throw any light upon the date of the foundation of Stonehenge, concerning which authorities vary in their estimate by some thousands of years. We beg to lay before the Royal Society the results derived from a careful study of its orientation for the purpose of arriving at the probable date of its foundation astronomically. This is not, indeed, the first attempt to obtain the date of Stonehenge by means of astronomical considerations. In Mr. Godfrey Higgins' work[2] the author refers to a method of attack connected with precession. This furnished him with the date 4000 B.C.

More recently, Dr. W. M. Flinders Petrie,[3] whose accurate plan is a valuable contribution to the study of Stonehenge, was led by his measures of the orientation to a date very greatly in the opposite direction, but, owing to an error in his application of the change of obliquity, clearly a mistaken one.

As the whole of the argument which follows rests upon the assumption of Stonehenge having been a solar temple, a short discussion of the grounds of this view may not be out of place; and, again, as the approximate date which we have arrived at is an early one, a few words may be added indicating the presence in Britain at that time of a race of men capable of designing and executing such work.

As to the first point, Diodorus Siculus (ii. 47) has preserved a statement of Hecatæus in which Stonehenge alone can by any probability be referred to.

"We think that no one will consider it foreign to our subject to say a word respecting the Hyperboreans.

"Amongst the writers who have occupied themselves with the mythology of the ancients, Hecatæus and some others tell us that opposite the land of the Celts [ἐν τοῖς αντιπέραν τῆς κελτικῆς τόποις] there exists in the Ocean an island not smaller than Sicily, and which, situated under the constellation of The Bear, is inhabited by the Hyperboreans; so called because they live beyond the point from which the North wind blows. . . . If one may believe the same mythology, Latona was born in this island, and for that reason the inhabitants honour Apollo more than any other deity. A sacred enclosure [νῆσον] is dedicated to him in the island, as well as a magnificent circular temple adorned with many rich offerings. . . . The Hyperboreans are in general very friendly to the Greeks."

The Hecatæus above referred to was probably Hecatæus of Abdera, in Thrace, fourth century B.C.; a friend of Alexander the Great. This Hecatæus is said to have written a history of the Hyperboreans: that it was Hecatæus of Miletus, an historian of the sixth century B.C., is less likely.

As to the second point, although we cannot go so far back in evidence of the power and civilisation of the Britons, there is an argument of some value to be drawn from the fine character of the coinage issued by British kings early in the second century B.C., and from the statement of Julius Cæsar (*de bello Gallico*, vi., 13) that in the schools of the Druids the subjects taught included the movements of the stars, the size of the earth and the nature of things (Multa præterea de sideribus et eorum motu, de mundi magnitudine, de rerum natura, de Deorum immortalium vi ac potestate disputant et juventuti tradunt.)

Studies of such a character seem quite consistent with, and to demand, a long antecedent period of civilisation.

The chief evidence lies in the fact that an "avenue," as it is called, formed by two ancient earthen banks, extends for a considerable distance from the structure, in the general direction of the sunrise at the summer solstice, precisely in the same way as in Egypt a long avenue of sphinxes indicates the principal outlook of a temple.

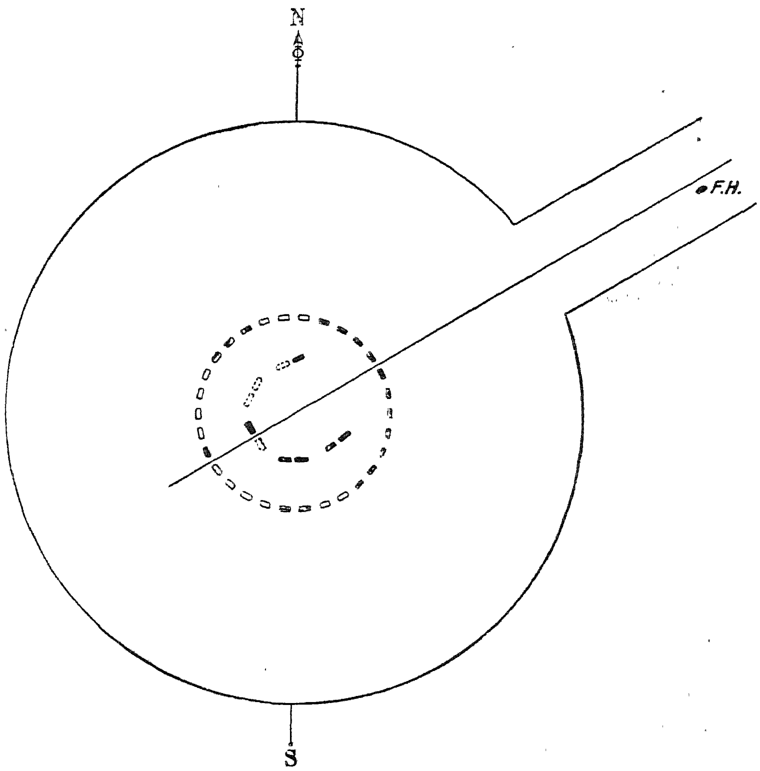


FIG. 1.—Plan of Stonehenge.

These earthen banks defining the avenue do not exist alone. As will be seen from the plan which accompanies this paper, there is a general common line of direction for the avenue and the principal axis of the structure, and the general design of the building, together with the position and shape of the Naos, indicate a close connection of the whole temple structure with the direction of the avenue. There may have been other pylon and screen equivalents as in ancient temples, which have disappeared, the object being to confine the illumination to a small part of the Naos. There can be little doubt, also, that the temple was originally roofed in, and that the sun's first ray, suddenly admitted into the darkness, formed a fundamental part of the cultus.

While the actual observation of sunrise was doubtless made within the building itself, we seem justified in taking the orientation of the axis to be the same as that

[1] By Sir Norman Lockyer, K.C.B., F.R.S., and F. C. Penrose, F.R.S., communicated to the Royal Society on October 19.
[2] "The Celtic Druids." 4to. (London, 1827.)
[3] "Stonehenge," &c. 1880.

of the avenue, and since in the present state of the south-west trilithon the direction of the avenue can probably be determined with greater accuracy than that of the temple axis itself, the estimate of date in this paper is based upon the orientation of the avenue. Further evidence will be given, however, to show that the direction of the axis of the temple, so far as it can now be determined, is sufficiently accordant with the direction of the avenue.

The orientation of this avenue may be examined upon the same principles that have been found successful in the case of Greek and Egyptian temples—that is, on the assumption that Stonehenge was a solar temple, and that the greatest function took place at sunrise on the longest day of the year. This not only had a religious motive; it had also the economic value of marking officially and distinctly that time of the year and the beginning of an annual period.

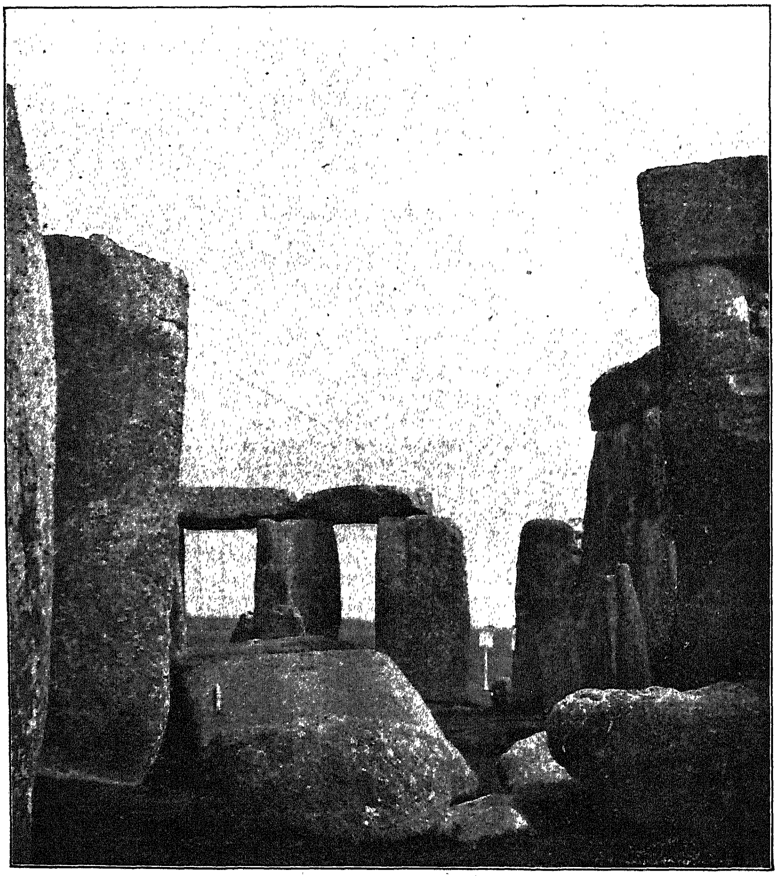

FIG. 2.—The Temple Axis (shown by the direction of the stake on the fallen stone).

It is, indeed, probable that the structure may have had other capabilities, such as being connected with the equinoxes or the winter solstice; but it is with its uses at the summer solstice alone that this paper deals.

There is this difference in treatment between the observations required for Stonehenge and those which are available for Greek or Egyptian solar temples—viz. that in the case of the latter the effect of the precession of the equinoxes upon the stars, which as warning clock stars were almost invariably connected with those temples, offers the best measure of the dates of foundation; but here, owing to the brightness of twilight at the summer solstice, such a star could not have been employed, so that we can rely only on the secular changes of the obliquity as affecting the azimuth of the point of sunrise. This requires the measurements to be taken with very great precision, towards which care has not been wanting in regard to those which we submit to the Society.

The main architecture of Stonehenge consisted of an external circle of about 100 feet in diameter composed of thirty large upright stones, named sarsens, connected by continuous lintels, and an inner structure of ten still larger stones, arranged in the shape of a horseshoe, formed by five isolated trilithons. About one-half of these uprights have fallen and a still greater number of the lintels which they originally carried. There are also other lines of smaller upright stones respecting which the only point requiring notice in this paper is that none of them would have interrupted the line of the axis of the avenue. This circular temple was also surrounded by an earthen bank, also circular, of about 300 feet in diameter, interrupted towards the north-east by receiving into itself the banks forming the avenue before mentioned, which is about 50 feet across. Within this avenue and looking north-east from the centre of the temple, at about 250 feet distance and considerably to the right hand of the axis, stands an isolated stone, which from a mediæval legend has been named the Friar's Heel.

The axis passes very nearly centrally through an intercolumnation (so to call it) between two uprights of the external circle and between the uprights of the westernmost trilithon as it originally stood. Of this trilithon the southernmost upright with the lintel stone fell in the year 1620, but the companion survived as the leaning stone which formed a conspicuous and picturesque object for many years, but happily now restored to its original more dignified and safer condition of verticality. The inclination of this stone, however, having taken place in the direction of the axis of the avenue, and as the distance between it and its original companion is known both by the analogy of the two perfect trilithons and by the measure of the mortice holes on the lintel they formerly supported, we obtain by bisection the measure (viz. 11 inches) from its edge of a point in the continuation of the central axis of the avenue and temple, and which has now to be determined very accurately. The banks which form the avenue have suffered much degradation. It appears from Sir Richard Colt Hoare's account that at the beginning of the last century they were distinguishable for a much greater distance than at present, but they are still discernible, especially on the northern side, for more than 1300 feet from the centre of the temple, and particularly the line of the bottom of the ditch from which the earth was taken to form the bank, and which runs parallel to it. Measurements taken from this line assisted materially those taken from the crown of the bank itself. With this help and by using the southern bank and ditch whenever it admitted of recognition, a fair estimate of the central line could be arrived at. To verify this, two pegs were placed at points 140 feet apart along the line near the commence-

ment of the avenue, and four others at distances averaging 100 feet apart nearer the further recognisable extremity, and their directions were measured with the theodolite, independently by two observers, the reference point being Salisbury Spire, of which the exact bearing from the centre of the temple had been kindly supplied by Colonel Johnston, R.E., the Director-General of the Ordnance Survey. The same was also measured locally by observations of the sun and of Polaris, the mean of which differed by less than 20″ from the Ordnance value. The resulting observations gave for the axis of the avenue nearest the commencement an azimuth o 49° 38′ 48″, and for that of the more distant part 49° 32′ 54″. The mean of these two lines drawn from the central interval of the great trilithon, already referred to, passes between two of the sarsens of the exterior circle, which have an opening of about 4 feet, within a few inches of their middle point, the deviation being northwards. This may be considered to prove the close coincidence of the original axis of the temple with the direction of the avenue.

This value of the azimuth, the mean of which is 49° 35′ 51″, is confirmed by the information also supplied from the Ordnance Office that the bearing of the principal bench mark on the ancient fortified hill, about eight miles distant, a well-known British encampment named Silbury or Sidbury, from the centre of the temple is 49° 34′ 18″, and that the same line continued through Stonehenge to the south-west strikes another ancient fortification, namely Grovely Castle, about six miles distant and at practically the same azimuth, viz. 49° 35′ 51″. For the above reasons 49° 34′ 18″ has been adopted for the azimuth of the avenue.

The present solstitial sunrise was also watched for on five successive mornings, viz. June 21 to 25, and was successfully observed on the latter occasion. As soon as the sun's limb was sufficiently above the horizon for its bisection to be well measured, it was found to be 8′ 40″ northwards of the peak of the Friar's Heel, which was used as the reference point, the altitude of the horizon being 35′ 48″. The azimuth of this peak from the point of observation had been previously ascertained to be 50° 39′ 5″, giving for that of the sun when measured, 50° 30′ 25″, and by calculation that of the sun with the limb 2′ above the horizon should be 50° 30′ 54″. This observation was therefore completely in accordance with the results which had been obtained otherwise.

The time which would elapse between geometrical sunrise, that is, with the upper limb tangential with the horizon, and that which is here supposed, would occupy about seventeen seconds, and the difference of azimuth would be 3′ 15″.

The remaining point is to find out what value should be given to the sun's declination when it appeared showing itself 2′ above the horizon, the azimuth being 49° 34′ 18″.

The data thus obtained for the derivation of the required epoch are these:—

(1) The elevation of the local horizon at the sunrise point seen by a man standing between the uprights of the great trilithon (a distance of about 8000 feet) is about 35′ 30″, and 2′ additional for sun's upper limb makes 37′ 30″.

(2) – Refraction + parallax, 27′ 20″.

(3) Sun's semidiameter, allowance being made for greater eccentricity than at present, 15′ 45″.

(4) Sun's azimuth, 49° 34′ 18″, and N. latitude, 51° 10′ 42″.

From the above data the sun's declination works out 23° 54′ 30″ N., and by Stockwell's tables of the obliquity, which are based upon modern determinations of the elements of the solar system,[1] the date becomes 1680 B.C.

[1] "Smithsonian Contributions to Knowledge," vol. xviii. No. 232. Table ix. (Washington, 1873.)

It is to be understood that on account of the slight uncertainty as to the original line of observation and the very slow rate of change in the obliquity of the ecliptic, the date thus derived may possibly be in error by ±200 years.

In this investigation the so-called Friar's Heel has been used only as a convenient point for reference and verification in measurement, and no theory has been formed as to its purpose. It is placed at some distance, as before-mentioned, to the south of the axis of the avenue, so that at the date arrived at for the erection of the temple the sun must have completely risen before it was vertically over the summit of the stone. It may be remarked further that more than 500 years must yet elapse before such a coincidence can take place at the beginning of sunrise.

We have to express our thanks to Sir Edmund Antrobus, Bart., for much kind assistance during our survey; and to Mr. A. Fowler and Mr. Howard Payn, for skilful and zealous cooperation in the measurements and calculations. As already stated, Colonel Duncan A. Johnston, R.E., Director-General of the Ordnance Survey, has also been good enough to furnish us with much valuable information, for which our best thanks are due.

TWO BOOKS OF TRAVEL.[1]

IN its general scope and character the first-named of these two works is very similar to Hudson's "The Naturalist in Plata"; the one giving as excellent a picture of wild animal life in the more remote parts of the United States as the other does for the Argentine Republic. Mr. Fountain, although evidently not a trained naturalist, appears to be an excellent observer of the habits of animals, and many of the facts he records, if not new, are certainly not matters of common knowledge. So far as the title is concerned, it might well be concluded that the work is a record of observations made during recent travel, but this is far from being the case, the author's journeys having been made during the 'sixties and early 'seventies, when a large part of the territory of the United States was more or less unexplored, and when the bison still swarmed in its untold thousands on the prairies. Consequently, in many respects, the observations on the fauna of the various districts traversed and on the habits and distribution of the larger mammals are far more valuable and important than any which could be made at the present day. It is perhaps to be regretted that greater pains were not taken to identify some of the animals referred to, which would have avoided certain corrections made in the appendix and have considerably increased the value of the work. Not improbably, however, the author may have had only his notes, and not actual specimens, to rely upon; and if this be so, he may well be excused the lack of the details in question. Taken altogether, with a certain allowance for more or less pardonable faults, it may truly be said to be one of the most delightful works of its kind that it has been our pleasure to read for a very long time, and it may be recommended to all lovers of Nature and a life in the wilds without a shadow of reserve.

To judge from its title (in the selection of which we think the author has scarcely done himself justice) the work might well have been taken for a record of travel, but, as a matter of fact, a very large proportion of it is

[1] "The Great Deserts and Forests of North America." By Paul Fountain. Pp. ix + 295. (London: Longmans, Green and Co., 1901.) Price 9s. 6d. net.
"Sunshine and Surf; a Year's Wanderings in the South Seas." By D. B. Hall and Lord Albert Osborne. Pp. xiv + 320. Illustrated. (London: A. and C. Black, 1901.) Price 12s. 6d.

devoted to natural history. In the first two chapters the author describes the leading features of the fauna of the Mississippi prairies at a time when, in many parts, it still existed in its pristine abundance. Like most amateur naturalists, Mr. Fountain is on the side of those who take a broad view of the limits of species, and we can fully endorse his remarks as to the close relationship of the American wolves to their Old World cousin. When, however (p. 5), he says that the American bison is a mere variety of the European species, and that the differences between the two animals are very slight, we take leave to differ from his opinions. And before putting in print a statement as to his doubts whether the number of ribs in the two is or is not identical, he might surely have taken the trouble to visit a good museum or consult some standard work on the subject.

A different phase of animal life is presented in the chapter entitled "A Day in a Cypress Swamp"; while in a later one (v.) we have many interesting observations on insects. The seventh chapter is devoted to the red man, who in some respects is viewed in a more favourable light than by many other writers. Of especial interest is the chapter headed "A Little Bit of the Desert," which is devoted to a description of Arizona and its fauna at the time when that State was an almost unknown land. This journey was made in 1871, only two years after Cope had described the poisonous lizard of Arizona, the so-called Gila monster (*Heloderma suspectum*), as a species distinct from the Mexican form. The author's account of its habits is probably one of the earliest on record, his description of how he found out its poisonous nature being an excellent instance of his careful observation.

The remaining three chapters deal with the Yosemite Valley and California and Colorado generally; and it is with a feeling of regret that limitations of space prevent our alluding to these otherwise than by name.

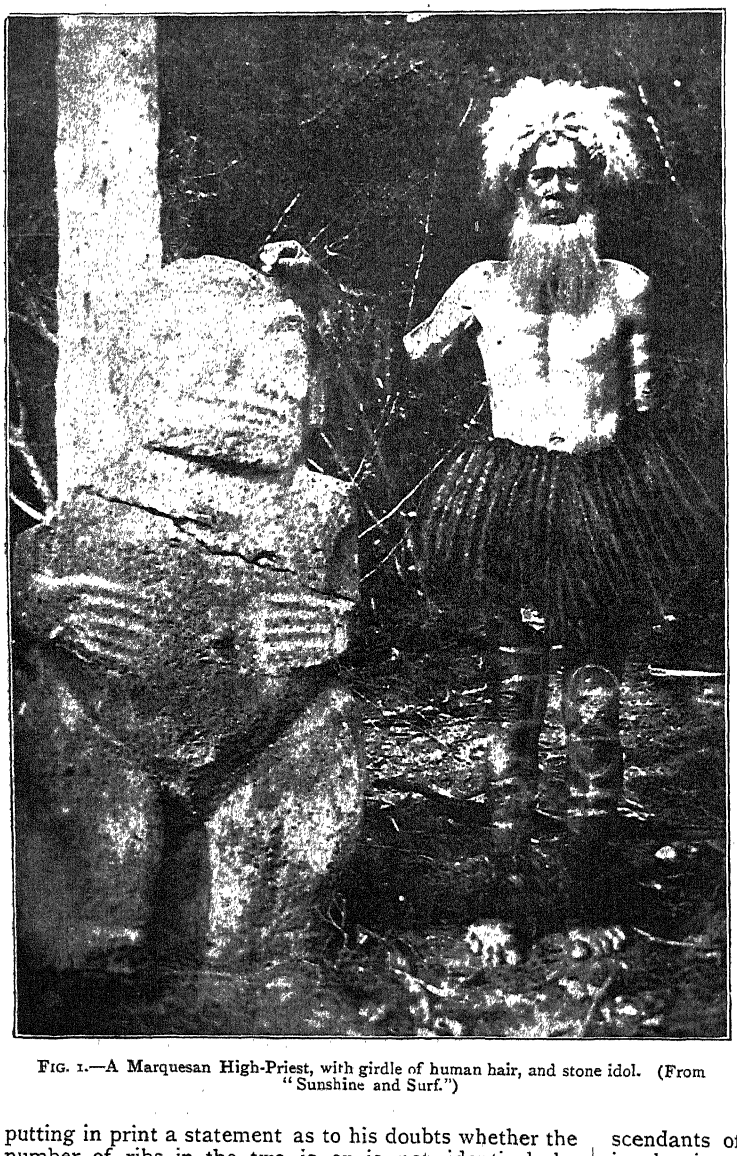

FIG. 1.—A Marquesan High-Priest, with girdle of human hair, and stone idol. (From "Sunshine and Surf.")

Very different in character from the first is the second of the two books named at the beginning of this notice, which is in the main the description of a trip to a number of the islands of the South Seas, with observations on their inhabitants and a few scattered notes on their natural history. Pleasantly written and beautifully illustrated, this work appeals more to the general reader and traveller than to the naturalist; and, in spite of the existence of such books as Kingsley's "The Earl and the Doctor" and Stevenson's "South Seas," both the former will scarcely fail to find much to interest them in its pages. The first visit of the authors was to Tahiti, with which they appear to have been as delighted—alike as regards scenery, climate and the people—as have all previous visitors. Of greater interest is the account of their visit to the Marquesas; and the excellent photograph of a Marquesan high-priest standing alongside a stone idol (herewith reproduced) should be of value to anthropologists as representing a phase of savage life rapidly on the wane. Among other interesting photographs, special mention may be made of one of a "Maori Belle" and a second of a "Samoan Beauty," the latter exhibiting the supreme development of the handsome Polynesian type. We should, however, like to know whether the Maori girl is pure-bred or a half-caste. In the islands under French rule, where it was formerly the universal custom, tattooing, the authors tell us, has been prohibited in the case of females, with a corresponding improvement in their personal appearance—at least from a European point of view. It may be added that much interesting information will be found with regard to the administration of the islands under French rule.

Much interest also attaches to the too brief remarks with regard to the feral goats, sheep and cattle—the descendants of animals introduced in 1813—now found in the interior of the Marquesas. The pleasures—and dangers—of reef-fishing are alluded to in some detail; and the authors endorse previous observations as to the diving powers of the natives, some of whom, they assert, are able to remain under water for four minutes at a time. A novel mode of shark-fishing, in which a diver fixes a running noose round the tail of the victim, is also described. But even in the South Sea Islands life has some drawbacks; and the authors speak in bitter terms of the miseries they

endured from sand-flies, centipedes and mosquitoes on certain islands, and from monstrous cockroaches on board the vessels in which they made some local trips. R. L.

NOTES.

THE close attention which the Emperor of Germany gives to scientific and technical subjects, and the personal interest he takes in the work of men who study them, have been shown on many occasions. The latest instance occurred on Monday, when, attended by a large naval staff, he was present at the annual general meeting of the Society of Naval Architects, founded three years ago on the plan of our own Institution of Naval Architects. The *Times* correspondent at Berlin states that the chief item in the programme was a lecture by Geheimrath Brinkmann on the changes which have been adopted in the disposition of guns in battleships and the results of these changes upon naval architecture. The lecturer pointed out the reasons which had caused the arrangement of the guns with the sole object of firing broadsides to be superseded. He spoke of the beginnings of independent systems of construction in Italy, in the United States and, to a certain extent, in Germany. In the course of the discussion reference was made to the advantage which Germany enjoyed in having the opportunity of constructing an entirely new navy while profiting by the experience of older naval powers, and it was pointed out that, as regards materials, German steel was excelled by none. To the surprise of the audience, the Emperor ascended the platform, and after beckoning all who were present to remain seated, spoke upon the subject of the influences of military requirements upon the development of naval construction and the disposition of artillery on ships. The presence of the Emperor at scientific and technical meetings is itself a mark of sympathy with their aims; and when, in addition, he shows himself keenly interested in the subjects discussed, the influence upon the public mind must be very great. To this influence must partly be ascribed the regard in which scientific investigation is held in Germany.

CONSIDERABLE interest attaches to a circular said to have been issued by the Italian War Office to the veterinary surgeons of the Italian Army. The circular recommends to their attention a new treatment for the so-called foot and mouth disease of cattle. The treatment was announced some little time ago by Prof. Bacelli, and consists in the intravenous injection of a solution of perchloride of mercury and sodium chloride. The intravenous injection of powerful antiseptics for specific diseases is, of course, not new. Quite recently intravenous injections of formic aldehyde were used, apparently with success, in the treatment of human pulmonary tuberculosis. We have not, up to the present, had access to the actual communication either of Prof. Bacelli or of Dr. Guzzi, who appears to have been the first to actually use the remedy in question; but it appears that the injected fluid consisted of 1 gramme of perchloride of mercury, 75 grammes of sodium chloride and 1 litre of water, and that of this solution first 30, then 50, then 70, and subsequently 100 cubic centimetres were injected. As the body-weight of the animals in question is unknown, an accurate estimation of the dose given is impossible. The ultimate remedial agent is the albuminate of mercury. The addition to the injecting fluid of the sodium chloride renders this substance more soluble, and also tends to prevent the precipitation of proteids by the perchloride, and hence the formation of emboli. The animals treated all appear to have been cured of the disease. From the general standpoint, these results, if accurate, are of interest in that they afford another instance of the possibility, by the intravenous injection of an antiseptic, of destroying, or at any rate influencing, the materies morbi without injuring the host.

A CORRESPONDENT informs us that the tercentenary of Tycho Brahe's death was celebrated in Basle, Switzerland, where Tycho settled for a time and revived interest in astronomical science. The Society of Naturalists of Basle met, with several other scientific societies, on October 23 in the Bernoullianum to listen to a lecture by Prof. Fritz Burckhardt on Tycho in Switzerland. A facsimile was shown of the letter, the original of which is preserved in the university library of Basle, with which Baron Hoffmann introduced Kepler to Tycho.

MR. A. J. EVANS, F.R.S., keeper of the Ashmolean Museum at Oxford, has been elected a corresponding member of the Munich Academy of Sciences.

WE learn from the *British Medical Journal* that on January 1, 1902, the Imperial Leopold Caroline Academy of Sciences, which has its headquarters at Halle, will celebrate the one hundred and fiftieth anniversary of its foundation. The Academy is the oldest scientific society in Germany.

THE seventh annual conference of hop growers will be held at the South-Eastern Agricultural College, Wye, on Wednesday, November 27. Colonel A. M. Brookfield, M.P., will preside, and reports will be presented on experiments conducted during 1901 on the manuring, drying, training and cultivation of hops.

THE adoption of the metric or decimal system of coinage, weights and measures in South Africa was advocated by Mr. Hutchins in a paper read before the South African Philosophical Society on October 2. It was shown that with very slight modifications the present coins and measures could be adapted to the decimal system. At the close of the meeting it was decided that a committee, consisting of Sir David Gill, Dr. Muir, Dr. Beattie, Prof. Thomson, Dr. Crawford, Mr. Littlewood and Mr. Hutchins (with power to add to their number), should prepare a report on the advisability of introducing or legalising the metric system of weights, measures and coinage in South Africa.

MR. J. STIRLING, Government Geologist and Mining Representative of Victoria, gave a lecture at the Imperial Institute on Monday on "Brown Coal-beds of Victoria, their Characters, Extent and Commercial Value." The question of utilising the large deposits of tertiary fuel known to exist in the Latrobe Valley, Gippsland, at Newport near Melbourne, Lal Lal near Ballarat, Dean's Marsh near Geelong, and at other places in Victoria, to commercial advantage in the interests of the State, is of considerable importance at the present time, when each portion of the Australian Commonwealth is taking stock of its natural resources. Geological sections run across the Latrobe Valley from north to south have disclosed the phenomenal thickness of the Morewell beds. A bore put down by the Government at Maryvale, near Morewell town, has proved 780 feet of brown-coal, in beds more than 260 feet in thickness. The chemical analyses of this fuel, taken from the bore at different levels down to 987 feet from the surface, have shown that its heat-giving qualities increase with the depth, there being from 36·75 per cent. of fixed carbon in the upper beds and 48·30 per cent. in the lower. Six hundred square miles of these tertiary brown-coal beds are known to exist in Victoria, of which 300 square miles, with 31,144,390,000 tons of the fuel, occur in the Latrobe Valley. From his intimate knowledge of these brown-coal deposits, and from the recent studies he has made on the Continent of Europe of the methods there adopted of utilising brown-coal by manufacturing it into briquettes, distilling paraffin and oils from it and producing various by-products, for all of which this class of fuel was especially adapted, Mr. Stirling has arrived at the opinion that Victoria possesses the makings of an

important national industry and that the establishment of various other industries round the centres where these brown-coal beds occur is only a question of time.

FROM a paper by Signor S. Cannizzaro in the *Atti dei Lincei* we gather that a movement is on foot in Italy for introducing the teaching of electrochemistry into the polytechnic schools of that country, and that the question has arisen as to whether this teaching should be placed in the hands of physicists or of chemists. In his paper, Signor Cannizzaro quotes the opinions of Oettel, Foerster, Lorenz, Lunge and Weber in support of the opinion that the subject falls within the domain of the chemist rather than that of the electrician.

TWO somewhat closely allied papers on Röntgen rays appear in the *Journal de Physique* for November, one by M. L. Benoist and the other by M. G. Sagnac. In the former the author finds that the general laws of transparency of different kinds of matter for Röntgen rays of different kinds can be reduced to simple forms, a result which is far from being true of other previously known forms of radiation. According to these laws the transparency depends only on the absolute and atomic weights, and it appears possible, when these data are known, to calculate the transparency of any body, however complex, for rays of given quality. On the other hand, the laws may be also taken as the basis of a classification of the rays themselves, and they suggest important applications to practical radiography and chemical analysis.

A NEW extensometer has been designed by Mr. H. T. Bovey for determining the longitudinal extension or compression of any given length of a horizontal beam loaded transversely. It consists essentially of two parallel overlapping steel bars the opposite ends of which rest by knife blades against two points on the specimen to be measured. Between the faces of the two bars is a small roller carrying a mirror. Any extension or compression of the specimen causes relative motion of the bars rotating the roller through a small angle which is readily observed by means of the mirror, the reading being effected by means of an ordinary telescope with cross hairs. In Mr. Bovey's paper, which is published in the *Transactions* of the Royal Society of Canada, experiments are described showing the variations in the position of the neutral surface in wooden beams bent by different loads.

SOME ten years ago the Berlin Meteorological Institute supplied a large number of rain gauges to the various German provinces with the view of supplementing the regular observing stations and of investigating the rainfall conditions. The fourth publication of this very useful series for the provinces of Brandenburg and Pomerania has recently appeared, having been, like the previous ones, officially prepared by Prof. G. Hellmann. The tables contain the average yearly values for 269 stations, and are very clearly represented on a map, showing by various degrees of tinting the differences of rainfall of various districts for each 50 millimetres between 450 and 750 millimetres. The mean annual value for the whole area is about 24 inches. The mean daily maximum falls amount to 1·08 inch, but the absolute daily maxima reach from 2·8 to 3·6 inches, and occasionally considerably higher. Heavy falls are much more frequent in the inland districts than on the coasts, owing to the greater frequency of thunderstorms in the former localities. The longest periods of drought are about thirty days on the coast and forty days inland, and the longest wet periods from twenty-five to thirty days. These valuable discussions may well serve as patterns for such investigations; they are beautifully printed, and issued at the low price of one mark.

IN this country we do not take much note of insect pests which damage violets, but this is not the case in the United States, where large quantites of these flowers are grown under-glass for commercial purposes. In *Bulletin* No. 27 of the Entomological Division of the U.S. Department of Agriculture, Mr. F. H. Chittenden describes a long list of insects deleterious to violets, roses and other garden plants. In the case of the violet, the worst appears to be the so-called "greenhouse leaf-tyer," which is the caterpillar of the moth *Phlyctaenia* (or, as Sir G. F. Hampson calls it, *Pioraea*) *rubigalis*, which eats away large patches from the under side of the leaves. English horticulturists are familiar with a closely allied species, *P. ferrugalis*. Various remedies are suggested for the ravages of these and other pests.

A SHORT time ago mention was made in these notes of a paper by Mr. J. J. Wilkinson on the pharynx of the "rat-tailed maggot," the larva of the fly Eristalis. To the last issue (vol. lxx. part 2) of the *Zeitschrift für Wiss. Zool.*, Dr. B. Wahl, of Graz, contributes an important memoir on the development of the hypodermal tissues of the imago in the same larva. In the same journal, Herr G. Rottmann publishes the first part of the results of his investigations into the development of the lingual ribbon, or radula, of the Mollusca, this part dealing with the cephalopods. Special interest attaches to his account of the growth and replacement of the teeth with which the radula is studded, the process being rendered clear by means of several figures in the text. A third article, by Dr. O. Maas, deals with the reproductive process in the sponges of the genus Tethya, which, as is well known, differ from all other members of the group in taking place by means of germinal buds. In another communication Dr. E. Wasmann completes his account of the parasitic flies recently discovered inhabiting the nests of white ants and named Termitoxenia.

THE *Monthly Review* for November contains an extremely interesting and well-illustrated article, by Mr. T. A. Cook, on the modern thoroughbred, dealing both with its history and its future prospects. From the evidence of contemporary documents, the author shows that the English horse previous to the introduction of the first strain of Arab blood must have been an animal endowed both with speed and endurance, and it was evidently one specially fitted to benefit by the cross in question, which has resulted, through a long and puzzling process, in the evolution of our present thoroughbred stock. Some attempts have been made to show that, because all the pedigrees of this stock can be traced back to Arab sires, the English thoroughbred is the product of Eastern blood alone, but this the author shows to be an untenable view. After noting the marked increase in the size of thoroughbreds since the date of the infusion of the Arab strain, Mr. Cook proceeds to inquire whether short-course two-year-old racing has had a deleterious effect on the endurance and stamina of the breed. On the whole, his conclusions with regard to this point are reassuring, and he notes with satisfaction a tendency at the present day to revert to long-distance racing. Should English thoroughbreds require fresh blood, the Arab strain at the present day would be useless, and it is considered that Australian and New Zealand sires would be most suitable for this purpose. Much stress is laid on the importance of preserving good portraits, and if possible models, of our best thoroughbreds; and it is suggested that when equestrian statues are made a well-known horse should be modelled. It is mentioned that in the statue of Charles I. at Charing Cross the charger is a model of a "great horse" from his Majesty's stables. The article concludes with some observations as to the best conventional mode of drawing running horses.

FROM Queensland we have received the Annual Progress Report of the Geological Survey for 1900, by Mr. W. H. Rands, Government Geologist, together with several detailed

reports by members of his staff. The chief attention of the Survey is appropriately given to questions of economic importance, but those of scientific interest are by no means neglected. Aid has been furnished by Mr. Robert Etheridge, jun., in the determination of a series of fossil corals from Stanwell, near Rockhampton, which prove to be of Permo-Carboniferous types. These are described and figured in *Bulletin* No. 12, together with a paper on the structure of the oolitic limestones by Mr. G. W. Card. The Etheridge and Gilbert goldfields in north-western Queensland are reported on by Mr. Walter E. Cameron. The reefs occur near the border of a mass of granite and lie partly in that rock and partly in adjacent schists. The same geologist has given attention to the artesian water in this northern area to the south of the Gulf of Carpentaria. The water-bearing strata occur at depths which extend to as much as 3000 feet beneath sea-level, and water has been obtained at depths of 2000 feet and upwards, with a yield varying from 100,000 to one million gallons a day. Mr. Cameron also reports on recent developments in the copper-mining industry in the Cloncurry district. The ores occur in the older metamorphic series, and further systematic explorations are strongly recommended. Mr. B. Dunstan describes the anthracitic coal-deposits of the Dawson-Mackenzie region in central Queensland; in the Annual Report of the Geological Survey of Queensland he also refers to the occurrence of rhodochrome and of barklyite (the opaque ruby). Mr. J. Malcolm Maclaren deals with the geology of the Ravenswood gold-field on the borders of the Burdekin River. The rocks comprise schists and altered sandstones of unknown age, quartz-porphyries, granitites and granites. Microscopic sections of some of the rocks are illustrated. The country rock of the reefs is mainly granitic. Mr. Maclaren reports also on the tin mines of the Stannary Hills, Eureka Creek, in North Queensland. The tinstone does not occur in fissure lodes with true walls, but as an impregnation along the bedding-planes of green chloritic slaty shales. Hence he considers that the permanency of the veins may be confidently anticipated. Mr. Lionel C. Ball reports on the Red Queen and Black Diamond gold-mines near Taromeo. The district is regarded as a promising one.

"APPENDIX No. 1—1902" of the Kew *Bulletin of Miscellaneous Information* has been issued. It consists of the usual list of seeds of hardy herbaceous annual and perennial plants and of hardy trees and shrubs, most of which have ripened in Kew during the year 1901. They are offered in exchange with Colonial, Indian, and foreign botanic gardens, as well as with regular correspondents of Kew.

THE Indian Tea Association has issued a report (published in Calcutta) on "Red Rust, a Serious Blight of the Tea-plant," by its scientific officer, Mr. Harold H. Mann. The disease is caused by an alga, *Cephaleuros mycoidea*, which attacks chiefly the leaves, one of the small number of algæ which are morbific parasites on plants. The remedy recommended is spraying with Bordeaux mixture or sulphide of potassium.

THE publication of the weekly *Botanisches Centralblatt* will cease with the close of the present year, when it will have completed its eighty-eighth quarterly volume. The chief editor, Dr. Uhlworm, has been chosen to edit a new international botanical journal, the publication of which was decided on at the recent Congress of Botanists at Geneva, subject to sufficient support being promised in the way of subscriptions.

WE learn from the *Botanical Gazette* that Dr. J. N. Rose has returned from his botanical expedition to Mexico. He has brought back a large collection of plants made chiefly in the States of Mexico, Hidalgo, Vera Cruz, and Pueblo. Considerable collections were made in the high mountains, especially about Pachucha and on Orizaba and Popocatepetl. The collection is especially rich in species of *Oxalis*, a genus which reaches a high development in Mexico.

STATISTICS issued by the Indian Department of Revenue and Agriculture show the mineral production of the Empire from 1891 to 1900. Of salt, about one million tons is annually produced; of saltpetre, about 20,000 tons. The output of coal has increased to more than six million tons. Gold has been produced to the value of about two millions sterling, mostly from Mysore. Burma and Assam have yielded 38,000,000 gallons of petroleum.

THE first number of a new periodical, entitled *Science, Arts, Nature*, has been received from Paris. The journal resembles *La Nature* in scope and typography, and the editor, M. Leon Lefevre, hopes to keep its readers in close touch with movements in science, invention and industry.

A SECOND edition of Mr. A. H. Hiorns's concise and practical manual on "Mixed Metals and Metallic Alloys" has been published by Messrs. Macmillan and Co., Ltd. The book has been completely revised and enlarged so as to include the results of the chief researches on alloys published during the last seven or eight years.

THE results of the Cambridge Anthropological Expedition to Torres Straits will be published in several volumes—probably six—dealing respectively with physical anthropology, physiology and psychology, linguistics, technology, sociology and religion. The first part, just published, belongs to the volume on physiolog and psychology, and in it Dr. W. H. R. Rivers deals with vision. We propose to notice the volumes when the series has been completed.

EVIDENCES of Austria's position among leading contributors to scientific knowledge is afforded by the annual volumes published by the Vienna Academy of Sciences. The *Sitzungsberichte* for 1899 are before us, and as they occupy approximately four thousand pages it is clearly impossible to describe the contents. Many of the papers have, however, already been mentioned in these columns, and we need now only express satisfaction at the substantial testimony to scientific activity presented to us by the volumes before us.

THE supplementary list of lantern slides just issued by Messrs. Newton and Co. contains, among other scientific subjects, sets of slides of natural history subjects reproduced from photographs by Mr. Douglas English; photographs of ripples on mercury and water surfaces by Dr. J. H. Vincent; sound waves by Prof. R. W. Wood; photo-micrographs illustrating the morphology of malaria by Dr. H. R. D. Spitta; and photo-micrographs by Dr. J. Leon Williams relating to the microscopic morphology and pathology of the enamel of teeth. To be able to illustrate lectures or lessons with these photographic pictures of natural objects and phenomena should greatly facilitate instruction and create interest in scientific subjects.

NEW editions of two volumes in the well-known Text-Books of Science series have been published by Messrs. Longmans, Green and Co. One is Sir W. de W. Abney's "Treatise on Photography," which contains the essential principles of the science of photography, and should be understood by everyone who aspires to be a successful photographer, whether from a scientific or artistic point of view. The second volume is Prof. W. A. Tilden's "Introduction to the Study of Chemical Philosophy," which has been completely revised and in large part rewritten in order to present the principles of theoretical and systematic chemistry in their modern aspects. The book is one which students of chemistry read with pleasure; because it is a synopsis of the leading principles of chemistry, and profit;

because it leads them to broad and philosophic views. Both books are tenth editions, a fact which shows that they have been appreciated; and doubtless they will maintain their high reputation for some time to come.

MESSRS. BREWSTER, SMITH AND CO. have sent us a pamphlet describing an improved form of sulphuretted hydrogen apparatus. The apparatus, which has been designed by Dr. F. M. Perkin, is so arranged that either a constant supply of the sulphuretted hydrogen gas or a saturated aqueous solution can be obtained. It is well known how rapidly an aqueous solution of sulphuretted hydrogen decomposes and becomes unfit for use. The new apparatus is so arranged that the surface of the solution has always an atmosphere of the gas over it, therefore no oxidisation can take place, and the solution is always saturated. The generating part of the apparatus is a slightly modified form of the apparatus first described by De Koninck, and contains a large supply of acid and of ferrous sulphide, so that when once fitted up it can be used for four or five months without being recharged. In this respect it is certainly an improvement over the "Kipp" apparatus, which requires constant recharging and wastes both of acid and sulphide.

THE additions to the Zoological Society's Gardens during the past week include a Squirrel Monkey (*Chrysothrix sciurea*) from Guiana, presented by Captain W. A. S. Copp; two Lesser White-nosed Monkeys (*Cercopithecus petaurista*) from West Africa, presented by Mr. P. Zaffere; two Laughing Kingfishers (*Dacelo gigantea*), a Black-backed Piping Crow (*Gymnorhina tibicen*) from Australia, presented by Captain Westcott; two Alligators (*Alligator mississippiensis*) from Southern North America, presented by Mr. Percival H. Hancock; a Common Snake (*Tropidonotus natrix*), British, presented by Mr. W. Swan Sonnenschein; a Pluto Monkey (*Cercopithecus leucampyx*) from West Africa, two Marica Gazelles (*Gazella marica*) from Arabia, a Common Roe (*Capreolus caproea albino*), European, deposited; four Lapwings (*Vanellus vulgaris*), European; fifteen American Mud Fish (*Amia calva*), twelve Long-eared Sunfish (*Lepomis auritus*), six Black Bass (*Huro nigricans*) from North America, purchased.

OUR ASTRONOMICAL COLUMN.

THE ANNULAR ECLIPSE OF THE SUN, NOVEMBER 10, 1901. —In the *Comptes rendus* (vol. cxxxiii. p. 768) there is a communication from M. Janssen stating that he has received by telegram notice of the success of the expedition sent to Cairo to observe the recent annular solar eclipse. He had requested M. de la Baume Pluvinel to photograph the spectrum of the solar light grazing the moon's limb; this had been done, and the photographs showed no trace of any absorption which might suggest the presence of a lunar atmosphere. M. Pasteur had obtained large-scale photographs of the sun with granulations. The result of the expedition was therefore to be considered entirely successful.

THE LEONID METEORS, NOVEMBER, 1901.—A telegram to the daily Press through Reuter's agency announces that a considerable number of meteors have been observed in localities where the weather conditions were propitious. Advices from many stations in the United States report more or less brilliant displays of the Leonids as having been seen on Thursday and Friday nights. A steamer from New Orleans reports having seen a great shower near Cape Hatteras early on Friday morning (November 15). The only night on which the sky was at all favourable in London was Thursday, November 14, and on that occasion continual watch was kept by three observers at the Solar Physics Observatory from 11 p.m. to 4 a.m. A few meteors were seen, from twenty to thirty, but nothing in the semblance of a definite shower was presented. Many of the shooting stars seen were very brilliant, but those traced out as being Perseids or Taurids were as numerous as those decidedly radiating from the sickle of Leo, so that probably there was nothing more than is to be seen on any good night for the same interval of time. Several photographic cameras were being exposed in different directions in the hope of recording trails, but without success. The 6-inch prismatic camera was adjusted some distance ahead of the radiant, on the star Pollux (β Geminorum), and a very bright meteor was observed to pass close to the star; but although special care was taken in development, nothing beyond the star spectrum was obtained on the plate.

STRUCTURE OF THE REGION AROUND NOVA PERSEI.— A considerable advance in the knowledge of the surroundings of Nova Persei has resulted from the examination of photographs obtained by Mr. G. W. Ritchey with the 24-inch reflector of the Yerkes Observatory. A reproduction of one of these photographs is given in the *Astrophysical Journal* (vol. xiv. pp. 167–168) in illustration of a short description of the appearances found on examining the negative. This photograph was obtained on the night of September 20, 1901, on a Cramer "Crown" plate of specially high sensitiveness, with an exposure of 3h. 50m.

The first glance at the photograph shows that the false penumbra which has been recorded with refracting telescopes is entirely absent. The image of the Nova is some 20″ in diameter on account of the long exposure, but there is little or no halo of nebulosity immediately about it. Completely surrounding the star, however, is a large elliptical belt of nebulosity some 20′ of arc in diameter, with patches of varying density, the most intense being on the southern half of the ring. These latter are probably identical with the four principal condensations mentioned by Prof. Perrine, the photographs of which with the Crossley reflector of the Lick Observatory show evidence of motion of these constituent portions of the nebula. As much of the finer detail is necessarily lost in reproduction, a drawing is appended showing the structure to be seen on the original negative. This shows the nebula to have a very complex structure, and the question as to whether it is spiral or consists of several annuli with interlacing branches cannot yet be decided. An exceedingly suggestive feature is the existence of two moderately dense wisps of nebulosity, extending from the Nova towards the west, which then curve towards the north and merge into the main convolutions of the nebula. A later circular just received from Kiel contains the important announcements that:—

November 12.—Ritchey states that a photograph obtained at the Yerkes Observatory on November 9 confirms the large motion of the nebula near the Nova.

November 13.—Ritchey finds the nebula surrounding the Nova probably expanding in all directions.

PROPER MOTION OF NOVA PERSEI.—Herr Östen Bergstrand, of Upsala, has computed a preliminary value of the proper motion of Nova Persei from measures obtained from photographs with the astrophotographic refractor at Upsala Observatory. The plates were taken on 1901 March 1, 11, and September 1, 11. The probable yearly proper motion is

$$\text{in R.A.} = \mu = -0\text{s}.\cdot 05$$
$$\text{,, Decl.} = \mu' = -0''\cdot 7.$$

The deduced mean position of the Nova is given as

$$\left.\begin{array}{l}\text{R.A.} = 3\text{h. } 24\text{m. } 28\cdot 16\text{s.}\\ \text{Decl.} = +43^\circ\ 33'\ 54''\cdot 0\end{array}\right\}\text{(Epoch 1901}\cdot 4.)$$

NEW VARIABLE STARS.—91 (1901) *Velorum*. Mr. A. W. Roberts announces the variability of the star having the position

$$\left.\begin{array}{lccc} & \text{h.} & \text{m.} & \text{s.}\\ \text{R.A.} = & 10 & 16 & 44\\ \text{Decl.} = & -41^\circ & 43'\cdot 8 & \end{array}\right\}(1875).$$

The changes observed indicate that the star is of the Algol type, with the following elements:—

Variation in brightness = 10·0–10·9 magnitude.
Period... ... ... = 1d. 20h. 30m. 2s.

92 (1901) *Coronae Australis*. The same observer also records as variable the star having the following position

$$\left.\begin{array}{lccc} & \text{h.} & \text{m.} & \text{s.}\\ \text{R.A.} = & 18 & 32 & 45\\ \text{Decl.} = & -37^\circ & 35'\cdot 8 & \end{array}\right\}(1875).$$

Variation in brightness = 8·0–9·0 magnitude.
Period... ... ... = about 185 days.

93 (1901) *Sagittae*. Herr F. Schwab, of Ilmenau, announces variability in the star B.D. + 19°·3975 :—

$$\left.\begin{array}{ll} \text{R.A.} = & 19^{\text{h}}\ 14^{\text{m}}\ 26^{\text{s}} \\ \text{Decl.} = & +19^{\circ}\ 25'\cdot 4 \end{array}\right\} (1900).$$

The variability is of the Algol type. Normally the star is about 6·5 magnitude, decreasing to nearly 9·0 magnitude, remaining here for some time and then rapidly increasing. At present there are not sufficient observations for stating a value for the period, but the light curve is similar to that of U Cephei, period 17 days. The last observed minimum was November 1 at 6·30 G.M.T. (*Astronomische Nachrichten*, Bd. 157, No. 3748).

DETERMINATION OF ORBITAL ELEMENTS.—In the *Astronomical Journal* (vol. xxii. No. 510, pp. 43–52) Mr. F. C. Moulton gives a general analysis of a method of determining the elements of orbits of all excentricities from the data supplied by three observations of position, and illustrative examples of the application of the equations derived to the cases of elliptic and parabolic orbits.

THE INTERNATIONAL MEETING OF PHYSIOLOGISTS AT TURIN.

THE fifth Triennial International Congress of Physiologists, which met at Turin in September, was the largest meeting of the kind that has assembled. The fine Institute of Physiology, under the direction of Prof. Angelo Mosso and belonging to the University, was put at the disposal of the Congress. In the neighbouring Institute of Histology was installed a museum for the exhibition of apparatus and preparations pertaining to physiology. The collection was extensive and important.

The number of communications announced for the sessions of the Congress was large enough to necessitate the institution of special accessory sittings. Sections were formed for Chemical Physiology and for Psycho-physiology. It is impossible in the space at our disposal to even mention all the material brought before the Congress, or to deal with any of the contributions fully. Preference was rightly given to communications illustrated by actual experiment or by actual preparations. A fuller verbal report has appeared in a special issue of the *Archives Italiennes de Biologie* (tome xxxvi. fasc. i.)

Among the communications coming under the head of Chemical Physiology the following may be noted.

Dr. Victor Henri (Paris) reported observations on the law of the quantitative action of sucrase. If a represent the quantity of saccharose at outset, and x the quantity inverted in a period equal to t, the action does not proceed in conformity with the logarithmic law admitted by authors, $K = \frac{1}{t} \log \frac{a}{a-x}$. The value of K does not remain constant during the reaction. The law in accordance with which the reaction proceeds corresponds with a formula, $K_1 = \frac{1}{t} \log \frac{a+x}{a-x}$. The *constant of inversion* K_1 varies with the concentration of the solution of saccharose a. The product aK_1 increases with a for weak concentrations (below 5 per cent.); it remains constant for concentrations of medium strength (5 per cent. to 25 per cent.) and diminishes when a increases above 25 per cent. The fact of having acted several hours and of being in a solution laden with invert sugar does not exert appreciable influence upon the activity of the sucrase.

Dr. Frederic S. Lee (New York) reported observations made by himself and Dr. C. C. Harrold on the influence of the ingestion of sugar upon *rigor mortis*. The prolonged administration of phloridzin to fasting cats causes the muscles to pass into *rigor* within a few minutes after death. If before death dextrose be given to such phloridzinised animals, the oncoming of *rigor* is delayed. The absence of carbohydrate from the muscle favours development of *rigor mortis*; it is, on the other hand, unfavourable to contraction.

Dr. F. S. Locke (London) demonstrated by a striking experiment the action of dextrose upon the activity of the mammalian heart. The heart removed from a freshly killed rabbit was washed free from blood and suspended freely, and arrangement made for recording its contractions by means of a lever attached to the apex. Kept at a temperature of 35° C., and fed with a modified Ringer's fluid, the contractions gradually grew feeble and ultimately very weak. If then oxygen under pressure were introduced into the fluid feeding the coronary arteries, the beats rapidly increased and remained good for an hour or so, and then once more diminished and failed. Dextrose then added to the feeding fluid to the extent of 1 per cent. restored the beat once more and it continued with hardly noticeable failure for ten hours or so. The beating fails at once if for the dextrose in the feeding fluid the oxygenated Ringer solution without any dextrose is substituted; but the beat is at once restored on returning again to the sugared fluid. Sucrose, lævulose and other sugars as yet tried fail to give evidence of this restorative power. The author must be congratulated upon the able and complete manner in which he demonstrated these important facts.

Prof. Albertoni (Bologna) communicated observations on absorption of various sugars from the stomach and intestine. The sugars (glucose, saccharose, lactose) were not absorbed in the ratio of their osmotic tensions. The absorption of lactose, whether in low tension or high tension solutions, was always less than for glucose or saccharose. In the intestine he always found a fluid of higher osmotic tension than the blood. During the absorption of sugar he found a slight increase of the osmotic tension of the blood.

Prof. Röhmann (Breslau) brought forward observations on the absorption of sugars from the intestine. Equal quantities of equally concentrated solutions of hexoses (glucose, galactose, mannose, fructose, and of pentoses (arabinose and xylose) placed in the small intestine (Vella's fistula) showed at the end of an hour loss by absorption of the different stereoisomeric sugars to very different extents. The absorption is, therefore, dependent, not only on the osmotic tension, but also on the configuration of the molecule of the sugar. The absorption of the disaccharides (saccharose, lactose and maltose) was further studied in respect to the extent to which their cleavage into monosaccharides went forward. It was found that a considerable though variable proportion of these disaccharides was absorbed without cleavage occurring in the intestinal canal. But an extract of the intestinal *mucosa* could produce the cleavage; probably the portion absorbed without being split up later underwent cleavage in the mucosa itself.

Dr. Nicloux (Paris) had studied the conditions of passage of carbonic oxide from the blood of the mother to that of the fœtus. He had employed for the determination of the quantities of the gas in the blood an accurate and delicate method elaborated in his previous experiments. When the percentage of CO in the air respired by the mother lay between $\frac{1}{10000}$ and $\frac{1}{1000}$, the quantities in the blood of mother and fœtus increased *pari passu* with increase of the percentage in the air respired, and the percentage in the fœtal blood was sensibly the same as in the maternal. With a percentage of above $\frac{1}{1000}$ of the gas in the respired air the identity of the percentage in the fœtal and maternal blood disappeared. This indicated a dissociation of the carboxy-hæmoglobin of the maternal blood at the placenta as a condition of passage across it. A simple experiment supports this view. A carp is placed in water to which has been added some oxycarbonated blood (dog's). The blood of the fish comes to contain a percentage of CO six or seven times greater than that of the medium of immersion. The animal shows no toxic effect from the immersion.

Dr. Pugliese (Bologna) had with Prof. Aducco found that the addition of sodium chloride to the water taken by fasting animals considerably increased their resistance to inanition. When the tissues of animals as similar as possible in other respects, but in the one case having water only, in the other salt and water, were analysed, the tissues under the latter condition were found to contain relatively the more water. Also the amount of water daily excreted by the animals receiving salt water was less than the amount of water excreted by those receiving water without salt.

Prof. A. Walther (St. Petersburg) demonstrated the action of Pawlow's *enterokinase* on fresh pancreatic juice as tested by digestion of measured quantities of fibrin. The conversion of the zymogen in the fresh juice into trypsin is not an oxidation process, for the *enterokinase* does not give the reactions of the oxidases, nor can the zymogen in the juice be rendered active by oxidising agents. The zymogen in the pancreatic juice is therefore not the same substance as Heidenhain's zymogen in extracts of the gland-tissue. The action of the *enterokinase* upon the zymogen is probably a hydrolytic one. From the fresh pancreatic juice a proteid (globulin?) can be precipitated

which has extraordinary tryptic but no amylolytic power; but the amylolytic power of the juice remains in the juice after removal of the tryptic proteid.

Dr. O. Cohnheim (Heidelberg) reported experiments on the disappearance of peptones placed under the influence of the intestinal *mucosa*. The peptones were not changed to albumin, but were split up into crystalloid cleavage products. This cleavage was accomplished by a ferment *erepsin* produced by the intestine, and active on peptone but not on albumin.

Drs. Delezenne and Drouin (Paris) had investigated the question of the origin of the pepsin which is secreted in urine. They found that that pepsin might have either or both of two sources, α, the pepsin secreted by the stomach and presumably reabsorbed, β, the pepsin known to exist in the muscles, salivary and other glands and organs. The authors demonstrated that the urinary pepsin had its origin in the gastric pepsin, and was obtained by reabsorption of that pepsin from the stomach itself. (1) In the dog after removal of the stomach, never under any condition of nutrition or in any digestive period is any proteolytic ferment whatever detectable in the urine. (2) In the dog after establishment of a gastric fistula and the prevention of the entrance of gastric juice into the intestine, the urine, as usual, contains pepsin. (3) In the dog after exsection of the stomach, the introduction of gastric juice into the intestine fails to result in the appearance of pepsin in the urine.

Dr. Drouin (Paris) had made observations to test the part played by the spleen (Schiff, Herzen) in pancreatic digestion. He had, in the dog, united the œsophagus to the duodenum and converted the stomach into an independent *cul-de-sac* opening on the surface by a fistula. Thus he eliminated gastric digestion altogether and left pancreatic action the chief *rôle* in digestion. He had then excised the spleen. The excision produced no appreciable difference in the assimilative powers, digestive activity or general well-being of the animal. The removal of the spleen seemed, further, in no way to alter the quality or quantity of the juice secreted by the fistulous stomach.

Prof. Gley (Paris) gave a *résumé* of his experiments and conclusions regarding the *rôle* and mutual interdependence of the thyroid and the parathyroid glands. The evidence was both chemical and histological. He regarded the parathyroids as complemental in function and structure to the main thyroid. He referred to the work done recently by Mr. Walter Edmunds (London), and a fuller summary of his communication can be found in an admirable article published by Prof. Gley recently in the English medical journals.

Prof. V. Ducceschi (Rome) communicated researches dealing with aromatic groups in the proteid molecule. Cinnamic acid could be obtained from egg-albumin and serum-albumin by a method which did not in that way split up tyrosin. It came probably from the aromatic group whence proceed in the putrefaction of some proteids phenylacetic and phenylpropionic acids; probably that group is phenyl-α-amidopropionic acid. From 500 grm. of egg-albumin, 2 grm. of β-phenylacrylic acid (cinnamic acid) are obtained.

Among other communications given in this section were those dealing with the speed of absorption and of elimination of acetylene gas by the organism (Prof. Ugolino Mosso, Genoa), the presence of lower homologues of caffeine and theobromine in certain plants (Prof. Albanese, Pavia), the pharmacodynamic action of acetyl chloride (Prof. Spineanu, Bucharest), the formation of fat in the animal body (Prof. Boruttau, Göttingen), the diastatic action of human saliva (Dr. Oehl, Pavia), the osmotic tension of milk, urine and amniotic fluid (Drs. Vicarelli and Cappori, Turin), electromotive changes observed in solutions of oxalic acid under exposure to light (Dr. Querton, Brussels), the fatty components in lecithin (Dr. Henriquez, Copenhagen), the influence of intestinal absorption on the diurnal curve of output of urea (Dr. Slosse, Brussels), the microchemistry of the cell (Dr. R. Kohn, Prague), a method for determination of the acidity of the gastric juice (Levi and Lolli, Modena), hæmolysmometry (Dr. E. Buffa, Turin).

Electrophysiology was represented, as regards special communications to the meetings of the Congress, chiefly by the papers of Profs. Boruttan, Fano, Herzen, Mislawski, Waller, Wedenskii and Weiss. The first named (Göttingen) demonstrated capillary-electrometer photograms of the action current of the frog's nerve obtained during strychnine tetanus. The frequency of the rhythm was about eight times per second, and the relative slowness of the curve was explicable by the imperfect synchronism of the course of the individual waves. Prof. Boruttan could not accept Sir J. B. Sanderson's suggested explanation of these strychnine oscillations of the electrometer line, and proposed to call them pseudotetanic. He finally entered upon the question of the proper functional rhythm of the nerve-cell.

Prof. Herzen (Lausanne) dealt with the separation of the action-current of nerve from the functional "impulse" of nerve. He appealed to, among other data, that of Boruttan's strychnine experiment, in which, from a partially dried nerve trunk incapable of transmitting the impulses from the strychnised centres to the limb-muscles, the transmission of the action-current was still demonstrably obtainable.

Dr. Waller (London) gave in two complemental reports a well-illustrated demonstrational *résumé* of the more recent of his work on the electric response of living matter, both plant and animal, to general and to adequate stimuli. New points were added to those already familiar to English students of the question. A comprehensive search has been undertaken into the distributional width of the existence of this "reaction of vitality" which he regards as coextensive with life itself.

Among points established by him were the following:—Mechanical excitation of a petiole renders the excited part electropositive to the unexcited. The illuminated part of a leaf is electropositive to an unilluminated. Electric stimulation of uninjured vegetable tissues is followed by an electrical response which is abolished at high and low temperatures, by anæsthetic vapours, and in consequence of strong electric excitation. A general relation between magnitude of response and "vitality" of plant or plant organ is noticeable, the stronger the "vitality" the greater the voltage of the response. This in seeds is confirmed by subsequent germination. Plant tissues when submitted to stimulation of uniform magnitude at regular intervals exhibit the characteristic changes known in animal physiology as "peripheral fatigue" and "recovery," "staircase effect" and summation. In consequence of one or more strong induction currents, the electrical conductivity of living plant tissues is greatly augmented. Among his observations upon animal tissues may be cited the following. The skin of the cat's foot gives an electrical response to excitation of the sciatic nerve; this current is ingoing, it has a latent period of about three seconds and an E.M.F. of a hundredth of a volt. In the skin of the frog's foot it can be shown that atropin abolishes this indirect response to excitation of the nerve. The electrical response of healthy excised human skin to electrical excitation of both directions is outgoing. Human skin continues to exhibit the outgoing response characteristic of the living state for 1–10 days after excision. Immersion in hot water at once destroys irrecoverably the power of the skin to respond. The electrical response of the skin and of the eyeball to direct excitation is comparable with similar effects witnessed in electrical organs.

Dr. Weiss (Paris) showed that if two successive electric stimuli be applied to a nerve at the same point of the nerve, the direction of the electric currents applied is important in determining the summation of the stimuli. If the electric stimuli are both of the same direction and occur within the duration of the latent period, the effect of the one is demonstrably added to the effect of the other. If they are, however, of opposite direction the stronger of the two is alone effective, at least if the weaker is subliminal it produces no obvious effect. That is, if the stronger of the stimuli is of just liminal value it remains of just liminal value whether preceded or followed by the weaker of opposite direction. The addition to it of the weaker in nowise changes the result produced by the stronger on the nerve.

Prof. Wedenski (St. Petersburg) drew attention to observations, conducted in his laboratory, indicating the fundamental similarity of inhibition of nerve to narcosis of nerve. He maintained that all general excitants of nerve exhibit three successive phases of influence upon nerve—a phase in which the rhythm of the excitation exhibits modification in the rhythm of the response, a phase in which there is a depression of conductivity of the excited state, a phase of depression of all response to excitation.

Prof. Vitzou (Bucharest) gave an account of experiments instituted to test the supposed inexcitability of the grey matter of the spinal cord to artificial stimuli. He claimed that his experiments demonstrate that the spinal grey matter, like the cerebral grey matter, is excitable by faradic currents.

Prof. Mislawski (Kasan) gave a communication upon the negative variation of reflex action. Du Bois Reymond's discovery

of the negative variation of strychnine convulsion, and Grützner's of that accompanying the spinal reflexes of the frog had shown the way to an electric examination of reflex action. His own observations exemplified how strictly the electric propagation through the reflex cell-chain conformed with the direction laid down by the Bell law of root-conduction. The electrical discharge in the reflex action he found to be an irregular one compounded of an irregular series of individual discharges.

Closely connected with such communications as these was a large group that may be classed as neurological. Prof. Langley (Cambridge) has begun an attempt to determine the group reactions to drugs and blood conditions of the different neurons which make up the nervous system. He demonstrated the stimulating action of nicotin on the neurons of the superior cervical ganglion in testimony of his view that that drug alters the cell-bodies (perikarya) of that ganglion. Since the suggestion of Carl Huber (Ann Arbor, U.S.A.) it has been customary to suppose that the incidence of action of nicotin in the sympathetic ganglia lies at the terminal fibrils of the preganglion neurons. Langley finds that if the preganglionic fibres are cut and allowed time for regeneration the local application of nicotin to the ganglion still produces its normal stimulating effect. Nicotin applied to a ganglion of the sympathetic chain causes erection of hairs only in the region supplied by the ganglion: if it stimulated the preganglionic nerve-endings axon-reflexes would move the hairs in other regions. Nicotin probably does not paralyse spinal ganglion cells; it does not stop the passage of impulses through the bipolar cells of the spinal ganglion of the skate. The erection of the hairs of the cat which occurs after asphyxia does not occur if the sympathetic pilomotor nerve-cells have been separated from the spinal cord; this blood stimulus acts, therefore, on the intraspinal pilomotor cells. Prof. Langley also spoke, in illustration of the same theme, of the effects of suprarenal extract on a number of tissues and organs where he had examined its action. His new results, together with others previously ascertained, showed that in all cases the extract produces an effect of the same kind as that produced by stimulation of the sympathetic nerve, and not like that produced by a cranial or sacral autonomic nerve. Notwithstanding this the action of the extract appears to be directly upon the tissue, not upon the sympathetic nerve-endings; thus it produces pallor and secretion of the submaxillary gland, and this after degeneration of the post-ganglionic fibres of the cervical sympathetic. The inhibitory effect of the vagus upon the cardiac sphincter of the stomach was demonstrated to the meeting.

Prof. Langendorff (Rostock) reported upon restoration of function which had occurred 105 days after total extirpation of the superior cervical ganglion of the cat. The signs of paralysis in the eye had then nearly passed off; they returned at once on section of the sympathetic nerve in the neck. Electrical excitation of the upper end of the cut nerve-trunk gave strong dilatation of the pupil, and palpebral fissure and retraction of *membrana nictitans*. Microscopical examination failed to reveal any reappearance or regeneration of the ganglion, but the sympathetic fibres must have found their way to their appropriate end-stations.

Dr. Bottazzi (Florence) reported observations on the innervation of the viscera in certain crustacea and in elasmobranchs. His communication was illustrated by a number of anatomical preparations and photograms showing the disposition of the nerve-trunks and the structure of the ganglia.

Dr. Marenghi (Pavia) demonstrated rabbits in which he had performed—as in one case was proved to the meeting by autopsy of an animal—intracranial section of the optic nerve, and still found persistence of reaction of the pupil to light and shade. The reaction was feeble and sluggish, but indubitable.

Prof. Flechsig (Leipzic) gave a very complete demonstration of preparations recording the history of the myelinisation of the nerve-fibres of the human brain. He described at considerable length, with the aid of projected slides, his views regarding the functional arrangement of different areas of the cortex cerebri. Cortical fields to the number of thirty-six, uniform in extent and distribution in different individual brains, can be mapped out by the myelogenetic method. These fields are divisible chronologically into three groups: primary 1–10, intermediate 11–31, terminal 32–36. The primary fields included the seats of cortical representation of all the senses. The myelinisation in each of the fields begins fairly contemporaneously throughout it and does not begin from a single point in it; neither the size of the nerve-fibres nor the vascularity of the tissue conditions the myelinisation of the area. Each primary field possesses a couple of well-defined conjugated tracts, one proceeding to it—cortico-petal and the earlier to myelinate—the other proceeding from it—corticofugal and the later to myelinate. The primary fields possess each a corticofugal tract which proceeds to regions non-cortical. The intermediate and terminal fields possess no such "projection" tracts. Prof. Flechsig regards both the cingulum and the fasciculus longitudinalis inferior as projection tracts from two of his primary fields; he believes, as Prof. W. H. Thompson has previously urged, that the latter tract connects the cortical visual field with the *corpus geniculatum laterale*. The intermediate fields, on the other hand, are rich in long association fibres leading to connection with other regions of the cerebral cortex.

Drs. Z. Treves (Turin) and A. Aggazzotti (Turin) reported the interesting results of an attempt to train the flight of a pigeon whose cerebral hemispheres had been removed. The bird, with another whose hemispheres were similarly removed at the same time, was allowed at first to remain, as pigeons after ablation of the hemispheres do, perched almost motionless on their wooden perch. The top of the perch offered an area some five centimetres by four. After some days it was removed from the top of the perch and placed about five centimetres from it, and was pushed towards it and in various ways incited to fly up to it. In fifteen days it began to take a short but fairly perfect flight to the perch-top. The distance was increased gradually by five centimetre increments. In five months' time by daily training the distance of flight had been extended to about eight metres. Sometimes the course of the flight was straight, often it was not so. Resting places were introduced sometimes not in a direct line to the perch in the cage. In six months' time progress had been made so far that the bird when thrown into air in a direction away from the cage orientated itself promptly and turned its flight in that direction. In nine months' time the bird flew regularly and well to the perch in the cage from any quarter of the room and when started in any direction. It, however, never once flew down from, or indeed left, its perch of its own accord, nor did it ever feed itself. From Turin it was taken to Modena for a fortnight and made to learn other exercises. On being brought back to Turin and liberated in its room it at once flew back to its cage and mounted its platform. It seemed to possess memory. The companion bird, to whom no training was given, at the end of nine months did not, when placed close to its perch and incited to fly to it, respond by flight, nor could it of itself, when placed just outside the cage, fly into the cage. Both birds retained throughout the strange huddled appearance and attitude characteristic of the pigeon after removal of the cerebral hemispheres.

Dr. A. S. Grünbaum and Prof. Sherrington (Liverpool) demonstrated a number of brains and cord-sections of anthropoid apes on which they had been investigating points in the physiology of the "motor area." Both excitation, by faradic electricity, and ablation had been employed. In view of the near approach of these brains to the configuration of the human it became obvious that the determination of the topography of the excitable and other areas must be in them of considerable practical importance to the study of human cerebral disease. They had at outset of their work been surprised to meet with results at variance with the topography generally accepted as probably obtaining in man. It had to be remembered, however, that the generally accepted topography was based chiefly on results obtained in the lower, not in the higher, apes, and that of the anthropoid apes only a single species, and that by a single specimen only, had previously been laid under experimental contribution. Their own experiments, embracing observations upon a series of chimpanzees as well as on the orang and the gorilla, were completely unanimous in denying any extension of the "motor region" to the surface behind the Rolandic fissure. Nor had they found the fissures in the motor region inexcitable, as had been asserted for the cortex of the orang, or that the motor region of the anthropoid required faradic currents much stronger than those required for the lower monkeys. A number of details were shown and dealt with in the communication, account of which limits of space preclude our here doing justice to. A chimpanzee taken to the Congress for actual demonstration of the excitation effects became ill on the journey and succumbed before experiment could be undertaken. We may remark that the research showed more clearly

than evidence hitherto accessible that in the motor region of these complexly folded higher brains the cortical fissures do not coincide with functional boundaries in the cortex, and that they do not, indeed, bear any accurately constant relation whatsoever to the functional topography. They are, with the exception of the Rolandic fissure itself, quite insecure landmarks to the details of the spatial arrangement of the functional "centres."

Prof. Nicolaides (Athens) demonstrated to the meeting two dogs in which he had performed bilateral vagotomy several months previously. He pointed out the remarkable subsidence of the symptoms that had occurred. His results, especially in regard to recovery from dyspnœic attacks, had, he contended, been considerably more favourable than those obtained by Pawlow.

Dr. Bayliss (London) gave an excellent demonstration of the antidrome vascular dilatation obtainable from the posterior spinal roots of the nerves of the pelvic limb. The excitation may be electrical, mechanical, chemical or thermal. The experiments leave no doubt that the vascular dilatation is brought about by impulses passing centrifugally along fibres of the sensory nerve-root, which, like the other fibres of that root, have their perikarya in the root-ganglion outside the cord. The fibres do not enter the sympathetic system, but proceed direct to the limb. Reflex vaso-dilatation of the limb can be produced after extirpation of the abdominal sympathetic, *i.e.* after all the vaso-constrictors have been removed; this dilatation must therefore be by means of vaso-dilator nerves which go to the limb through the hindmost three lumbar and first sacral nerves. Similarly, vaso-dilator fibres pass to the forelimb by the hindmost three cervical and first thoracic nerves.

Dr. Bocci (Siena) showed tracings demonstrating the diminution in the excitability to electric stimuli of the nerves of the frog produced by destruction of the spinal cord.

Dr. S. A. Dontas (Athens) demonstrated the different character and the greater degree of mechanical elasticity possessed by a muscle before than after poisoning by curare.

Drs. Negro and Z. Treves (Turin) demonstrated graphic records of the willed muscular contractions performed by a patient suffering from Parkinson's disease (*Paralysis agitans*). These records showed that the oscillations which, as Schäfer and v. Kries have shown, normally characterise willed contractions and normally succeed at a rate of 10–12 per second in the patient with *morbus Parkinsonii*, occur at a rhythm of only 5–6 per second.

Dr. Demoor (Brussels) showed preparations illustrating some remarkable sequelæ to trepanning in young animals. The brain had been in some way injured at the operations, yet at the end of about five months wasting of the body with epileptiform seizures ensues and death soon follows. The cells of the cerebral cortex are found to be in a condition of chromolysis with a moniliform degeneration of their dendrites.

Other communications dealt with the differential reaction of muscle and nerve (Mdlle. Joteyko, Brussels), graduation of the effects of fatigue (Mdlle. Joteyko, Brussels), the *rôle* in respiration of the sensory nerves of the diaphragm (Mislawski, Kasan), cerebellar tonus (A. Moscucci, Siena), the coordination of antagonistic muscles (Victor Henri, Paris), the phenomenon of Bell (C. Negro, Turin), conditions favourable and unfavourable to hypnosis in the frog (M. Stefanowska, Brussels). Among contributions to method may be mentioned Dr. Treves's improvements in the ergograph of Mosso, Dr. Broca's (Paris) apparatus for obtaining constant condenser discharges at any desired rate of frequency, and Dr. Corona's ingenious trephining instrument.

Among communications dealing with muscle may be cited Dr. F. S. Lee's (New York) observations with Dr. W. Salant on the influence of doses of alcohol upon the contractions of the directly excited isolated muscles of the frog. It was found that alcohol in minute doses seemed to favour the response of the muscle, in larger doses it was obviously deleterious. Dr. J. Demoor (Brussels) demonstrated his method and some of his results upon the dissociation of contraction and conduction in the muscle of the frog. The muscle is surrounded with plaster of Paris for half its length. The electrodes being placed on the free part of the muscle, a series of contractions in that free part is provoked and repeated to the production of fatigue. The plaster is then broken from the other half of the muscle and that half is found to be quite unaffected by fatigue. If the stimulating current be applied to the part within the mould instead of to that outside, the latter contracts in response to the stimulation and can be reduced to inexcitability by fatigue. But the part inside the mould, although it has served as conductor to the fatigued part, is found to have remained inappreciably affected by fatigue. Prof. Huerthle (Breslau) demonstrated a series of remarkable microphotograms of muscle fibre at rest and in contraction, examined under illumination by homogeneous light and by plane polarised light with an analyser.

Prof. Langendorff (Rostock) had examined the direction and speed of the conduction of the contraction-wave over the heart by applying to the surface of the isolated and artificially fed cat's heart two rheoscopic muscle-nerve preparations from the frog. The two preparations were 2 to 3 centimetres apart. The wave of negativity was found to sweep usually—if heart were beating well—from the base toward the apex, at a speed of 2 metres per second. If the heart were beating badly it might be as slowly propagated as ½ metre per second.

Prof. Blix (Lund) demonstrated apparatus devised for myothermal experiments on excised frog muscle; and apparatus for a similar purpose was also demonstrated by Dr. Bürker (Tubingen). Prof. Blix also showed a new form of induction excitator used by him in his more recent work on the summation of twitches.

Dr. Negro (Turin) demonstrated a fine series of microscopical specimens displaying the motor end-plates in mammalian and reptilian muscle-fibres.

Prof. Grützner (Tubingen) communicated the results of an investigation he had conducted upon the movements of the contents of the stomach and the regional distribution of the acidity of the semi-fluid mass of food occupying the cavity of the organ. The method employed had been rapid removal and freezing of the viscus and then its examination by frozen sections cut in various planes. When solid or semi-solid food is taken, that which is later introduced is always found toward the centre of the cavity of the organ. The contents of the pyloric end were always well acidified throughout, those of the cardiac end only in the layers nearest to the mucosa. The movements of the stomach seem to result in the food being deposited in layers upon the surface of the mucosa and that layer next to the mucosa being shifted toward the pylorus.

Prof. Zuntz (Berlin) described the methods employed by himself and his four colleagues, Caspari, Waldenburg, Lœwy and Kohner, in their recent research into the chemical metabolism of the body at high altitudes, namely on Monte Rosa. Dr. v. Schrötter (Vienna) reported his observations of some of the physiological phenomena attending a balloon ascent to an altitude of 7500 metres.

Of experiments dealing with the circulation, a large number were demonstrated. Prof. Hürthle (Breslau) demonstrated his new Stromuhr in action on the living animal, also a number of the graphic records obtained by it. These proved (1) increase in speed of flow of the blood in the carotid, produced by compression of the opposite carotid, (2) increase by section of the vago-sympathetic, (3) slowing of the blood stream in the crural artery as a result of tetanisation of the limb muscles by stimulation of their nerves, (4) the blood stream in the arteries as measured by the volume of blood flowing along the channel in a given time increases, not in simple proportion to increase of the arterial pressure, but in much greater ratio, *e.g.* blood pressure 87 mm. Hg., stream volume 400 mm^3., b. press. 131 mm. Hg., stream volume 1000 mm^3., b. press. 161 mm. Hg., stream volume 1500 mm^3.

Dr. T. G. Brodie (London) demonstrated a new method for investigation of effect of drugs on the mammalian heart. The mean pressure against which the heart works is kept constant and the work determined by the product of the output and of the mean pressure. An automatically working "Stromuhr" registers the output. Of the results obtained, especially noteworthy were those concerning anæsthetics. Chloroform depressed the working capacity vastly more than did ether or ethylene chloride. Suprarenal extract much increased the amount of work performed by the heart, as also its rate of beat. Suprarenal extract acts as an antidote to chloroform. If administered before chloroform it is found that the heart can withstand much larger doses of chloroform. Moreover, a heart deeply injured by chloroform will rapidly and completely recover if suprarenal extract be administered. It had in the course of the research been constantly found that the heart was very sensitive to the blood of different mammalian species, thus the heart of the dog went quickly into fibrillar incoordination unless fed with dog's blood; ox blood and other kinds of blood acting deleteriously at once. Dr. Brodie also showed his apparatus for the recording of the lung volume. He employs a plethysmographic method,

which he demonstrated in use. Dr. Dixon (Cambridge) is his collaborator in the research not yet completed, for which the apparatus was designed.

Prof. Fano (Florence) described at some length a series of electrometer photograms registering electromotive phenomena of the heart beat. The photographic records shown in illustration of several new points he brought forward were particularly fine specimens of what such records can be in the hands of the skilful.

Prof. Moussu (Alfort) had studied the lymph flow in the limbs of the larger animals (horse, ox, &c.) during physiological repose and inaction, and then under conditions of local vasoconstriction and vasodilatation and under those of general augmentation of blood pressure and of copious venous depletion. He had further observed the lymph flow under the influence of muscular work and under conditions of great activity of the tissues in general. A very large series of observations was presented in a number of tables together with diagrams of the apparatus employed for measuring the quantities of mechanical work given by the animals in certain of the experiments dealing with the effect of muscular activity. The conclusions arrived at were (1) that the lymph is not the simple product of a transudation from the blood plasma through the capillary wall under the mechanical pressure of the blood-circulation; (2) that filtration is always quite a minor factor in the production of lymph; (3) that the lymph is mainly a product of the tissues comparable to a secretion from them; (4) that the quantity of its production is in direct relation to the functional activity of the tissues; (5) that the peripheral (limb) lymphatic apparatus is in large measure an apparatus for excretion.

Prof. Stirling (Manchester) demonstrated his simple and successful method of injecting the sublingual lymph-sac of the frog and of applying drugs to the muscles related to it. Fluid, *e.g.* solution, of Berlin blue is injected under slight pressure into the dorsal lymph-sac and finds its way to the sac below the tongue. Excellent anatomical preparations are thus obtainable; drugs, *e.g.* veratrin, may thus be applied directly to the hyoglossus *in situ*.

Prof. Kemp (Illinois) on behalf of Miss Calhoun and himself made an interesting communication upon blood-platelets and their relation to coagulation of the blood-plasma. After thorough control of the method for fixing the platelets they attempted their methodic enumeration. The number varied between 961,500 and 730,000 per cub. mill. in man; a larger number than they found in dogs. The authors confirmed Bizzozero's observation that if the blood of the living dog be reduced to an incoagulable condition by repeated "whippings" and reinjections the incoagulable blood contains no platelets. But it contains some, though few, leucocytes. The authors find that in normal clotting the blood-platelets break down, the leucocytes do not. The fibrin filaments radiate from disintegrating blood-platelets at the nodes of the network they form.

Prof. Hédon (Montpellier) showed that the hæmolytic glucosides are more globulicidal in saline solutions than in serum. Substances therefore exist in the serum that may be regarded as protecting the red corpuscles against the toxicity of these glycosides. A little serum added to the water in which they are swimming protects tadpoles against the toxicity of glycosides (saponine, cyclamine) that are otherwise violently poisonous for them. Similarly, acid sodium phosphate protects the red corpuscles from the action of solanine and protects fish if added to the water of the aquarium.

The large attendance of active workers in the field of sense-organ physiology and in pyscho-physiology was a notable feature of the Congress, and the communications made upon those subjects were numerous. Dr. Tschermak (Halle) gave a lucid account of interesting and exact work upon the extent of the binocular field of vision in various vertebrate types. Prof. Hensen (Kiel) demonstrated experiments in evidence of an accommodation mechanism for the ear. Prof. Cavazzani (Ferrara) demonstrated an instrument for the estimation of the visual purple. Dr. Sante de Sanctis (Rome) reported the results of prolonged researches upon the depth of sleep. The stimulus required to break sleep was found usually to be greatest in the first half of the second hour. The increase of stimulus required to pass from provocation of a subconscious reaction to actual waking amounted on an average to three degrees of the scale of the Griessbach æsthesiometer. Prof. Osawa (Tokio) described observations indicating that most monkeys are right-handed, only a few left-handed; that birds, on the other hand, are usually left-footed. Drs. Broca and Sulzer (Paris) communicated a research into the latent period for visual acuity. Dr. S. Vaschide (Paris) had made numerous measurements of the simple reaction time for olfactory sensations. Dr. Marco Treves (Turin) reported observations on the thermo-esthesiometry of the various mucous membranes accessible to external examination. The sensitivity was in all cases found to be markedly less than is that possessed by the skin. The mucosa of the urethra and of the cervix uteri were quite incapable of heat and cold sensations, and even the cautery excited only slight, and that painful, sensation from them.

Dr. Kiesow (Turin) brought forward observations proving that the laryngeal aspect of the epiglottis is endowed with sentiency for taste, and so also the greater part of the mucosa lining the interior of the larynx itself. The whole of the soft palate (but not the hard palate) and the back of the pharynx were found endowed with taste. On the other hand, taste sensations could not be evoked from the uvula, the tonsils, the anterior or posterior pillars of the fauces. In regard to other species of sense, the uvula, tonsils and pillars of the fauces were found to be very defective in regard to touch and temperature stimuli, but fairly responsive as regards "painful"; the combination of sense-organs is in this respect almost the converse of that obtaining on inner surface of the cheek. Dr. Kiesow gave further communications upon the "temperature spots" of the skin. He laid stress upon the considerable amount of evidence that the "cold spots" lie much nearer the surface of the skin than do the "hot spots." Regarding the topographical distribution of the spots, his own very extensive observations differed in no important respect from those of Blix and Goldscheider, but in detail agreed better with those of the former, although he did find the cold spots rather more sparse than had Blix.

Dr. Kiesow also brought forward an important result for which his observations on "touch spots" gave basis, namely, that the value of the median threshold of the touch spot is within narrow limits practically the same for all touch spots the whole body-surface over. This is in strong contrast to the wide variation which the median threshold for pain exhibits. This discovery is of much significance for the analysis of spatial perception.

Among those present, in addition to those mentioned above, were Profs. Aducco (Pisa), Albanese (Pavia), Albertoni (Bologna), Axenfeld (Perugia), de Burgh Birch (Leeds), Bohr (Copenhagen), Bowditch (Boston), Chauveau (Paris), v. Cyon (Territet), Dastre (Paris), Dupuy (Paris), Ebbinghaus (Breslau), Einthoven (Leyden), Fano (Florence), Foster (Cambridge), Fredericq (Liege), Gad (Prague), Gaule (Zurich), Gley (Paris), Golgi (Pavia), O. S. F. Grünbaum (London), Héger (Brussels), Henriquez (Copenhagen), Hering (Prague), Hopkins (Cambridge), Johansson (Stockholm), Kossel (Heidelberg), Kronecker (Berne), Laulanié (Toulouse), Lépine (Lyons), Lombard (Ann Arbor, U.S.A.), Luciani (Rome), Marey (Paris), Nicolaides (Athens), Oehrwall (Upsala), Onimus (Munich), Osawa (Tokio), Perroncito (Turin), Physalix (Paris), Prévost (Geneva), Querton (Brussels), Sergi (Rome), Shore (Cambridge), Sowton (Liverpool), Stafford (Nottingham), Starling (London), Stefani (Padua), Stirling (Manchester), v. Tarchanow (St. Petersburg), Thompson (Belfast), Tigerstedt (Helsingfors), Toulouse (Paris), Tschermak (Halle), v. Uexkull (Naples), Verworn (Göttengen), Vintsgau (Innsbrück), Welby (London). The Congress was more numerously attended than any previous one. The courtesy and hospitality of their Italian colleagues will always remain a memory with the members present. The Italian committee consisted of Profs. Aducco, Cavazzani, Corona, Fano, Luciani, Angelo Mosso, Patrizi, Sertoli and Stefani. Drs. Treves and Herlitzka proved indefatigable local secretaries. The Italian language was an official language for the Congress, and it was formally decided that it should henceforth remain so.

ON A LATE PLEISTOCENE DEPOSIT CONTAINING MAMMOTH.

AMONG the districts in which there is a fair probability of obtaining satisfactory evidence as to the sequence of events which have occurred since the glacial episode, there is none more promising than the northern part of East Anglia, nor is there any region where the history of that early post-Glacial age, if it could be clearly made out, would throw light upon so many vexed questions in geology.

It is therefore very desirable that any new bit of evidence bearing upon the case should be placed on record, and, from this point of view, a discovery recently made at Didlington Hall seems to be of value, especially as the conditions which it indicates are exceptional in the district and the facies of the animal remains found is unusual. The bones and shells were carefully collected by Lady Amherst and are now preserved in the museum at the Hall.

Didlington Hall is built on the margin of an extensive bed of Boulder Clay, into which the river has cut back, forming a cliff which now rises from 26 feet, the level of the water in the lake, to about 38 feet above ordnance datum. It is no longer seen as a cliff just here, because the original form of the ground has been much modified by natural and artificial operations. Down the valley, however, this cliff forms a well-marked feature along the right bank, but up stream it is generally softened down into a gentle slope. Owing to the overlap of the artificial soil and rainwash near the Hall, nothing was known of the character of the marginal deposits of the river until, in carrying out some alterations in the boat-house, it was found necessary to cut off and dry a portion of the bed of the lake and remove some of the clay close to the original bank.

The lowest part of the bed was full of large stones out of the Boulder Clay, most of them covered with glacial striæ. With them were the bones of large animals which had probably been also washed in from the bank in floods. It appeared to be a deposit thrown down in an embayed curve of the river, perhaps even cut off from the stream so as to form a pond or "broad." The velocity of the stream cannot have been great, for the rest of the deposit consisted of fine blue mud and the shells were well preserved, as were also the plant remains, though these were very fragmentary. There were, moreover, no signs of sorting by water in any part of the deposit exposed, which was not more than 18 inches or two feet in thickness. The river must have been diverted or its velocity somehow checked and this small patch left as a record of some of its latest efforts in this part of the valley.

This clay was covered by a few feet of later deposits from the existing lake, and was penetrated by the roots of water lilies and other aquatic plants.

The following shells were found in it and determined by Mrs. McKenny Hughes:—*Sphaerium Corneum*, Linn., *Pisidium amnicum*, Müll., *P. fontinale*, Drap., *Unio sp.* fragments only, *Bythinia tentaculata*, Linn., *Valvata piscinalis*, Müll., *Planorbis carinatus*, Müll., *Limnaea peregra*, Müll. (several varieties), *L. auricularia*, Linn. (and varieties), *L. stagnalis*, Linn., *L. palustris?* Müll., *Succinea putris*, Linn., *Helix* (*Fruticicola*) *hispida*, Linn., *H.* (*Xerophila*) *Ericetorum*, Müll., *Pupa marginata*, Drap. The larger animals were:—*Elephas primigenius*, *Equus caballus*, *Bos longifrons*. *Cervus elaphus* of very large size has been found in a similar deposit in the immediate neighbourhood.

We notice the absence of the older forms of Bos, viz. *Bison priscus* and *Bos Urus*; whereas a strain of *Bos longifrons* occurs here, though it has never been found associated with the mammoth in the gravels.

Bos longifrons has not yet been satisfactorily described. There is certainly a larger and a smaller variety in the peat of both Ireland and England, but whether they were wild or all domesticated or derived from a domesticated breed is not clear.

It may be that further search would yield some of the forms whose absence we remark, but the evidence, so far as it goes, points to the Didlington Clay being more recent than the gravels in which the mammoth occurs elsewhere in East Anglia. It might be, of course, that it was made up of the washings of earlier deposits of various age, but there is nothing in the condition of the mammoth bones to suggest that they are not of the same age as the other remains found here. Moreover, several consecutive vertebræ of the mammoth found together in their natural order prove that the ligaments had not perished when the bones were buried in the clay.

Some of the bones, especially those of horse, were grooved and striated in such a manner as to remind one of ice action, and of course the close proximity of the Boulder Clay suggested the possibility of their being derived from it; while we have to bear in mind also the probability of the agency of river ice at a later period.

On the other hand, similar striæ on the bones found in other sections in East Anglia have undoubtedly been caused by settlements in the stony mass by which the gravel has been squeezed against and even into the inside of the bones while the process of decomposition was going on. This fact and the occurrence of similar striæ on the bones of saurians in Jurassic clays throw great doubt upon the inference that the scratches on the Didlington bones are due to any kind of ice action. None of the plant remains have been determined.

There is much evidence in favour of the view that after that not so very remote yet very exceptional episode, in which glacial conditions prevailed over this area, the whole of the district stood at a higher level. Then the basin of the Wash and its tributaries was re-excavated and extended, and a considerable resultant river found its way into the sea through the chalk escarpment between Hunstanton and Skegness. Into this river the Wissey and other streams of west Norfolk found their way. Some time later the area was depressed, and the rivers, which had descended with considerable force, especially in times of flood, were met by the tides at higher and higher points as their valleys gradually sank to sea-level. But this was not a sudden or even a rapid change, and the species of plants and animals disappeared by degrees as the conditions became unsuited for them. The Didlington Clay belongs to this period of changing conditions and is a late Pleistocene formation laid down after the arrival of *Bos longifrons*, but before the mammoth had ceased to inhabit, or at any rate to be a visitor in, the district.

Almost all the remains of the earlier Pleistocene times have been obtained from sands and gravels of a torrential character, and we have seldom had any opportunity of examining the embayed corners where they have been preserved in fine mud. This is partly due to the fact that the sand and gravel are of commercial value, but the mud is only excavated to get at something below it, as, for instance, at the marl for cement, or the gault for bricks, or, as in the case to which attention is now called, where the excavations were made for a new boat-house which exposed this blue river clay at Didlington Hall.

But another, and perhaps the more common, reason is that it was generally near the mouths of the sinking river valleys which have been since submerged and buried under later deposits that the velocity of the stream was checked so as to allow of the deposition of fine mud instead of sand and gravel.

T. McKENNY HUGHES.

SOME SEASONAL VARIATIONS IN THE BRITISH ISLES.

IN a paper just published by the Royal Society[1] attention is directed to a peculiarity in the seasonal variation of temperature in the British Isles disclosed by the resolution into harmonic components of the curves of day to day variation derived from the 25-year means of the 24-hourly readings at Kew, Falmouth, Aberdeen and Valencia. The peculiarity in question is the second harmonic component which is represented by a curve with two maxima and two minima in the year. In the 25-year curves for each of the observatories the maxima of the second components come within four days on either side of January 31 and August 1 respectively, and the minima are in the first week of May and November. They represent a temperature effect which exaggerates the height and shortens by nearly two weeks the duration of the summer portion of the compound curve; it also moderates the depth and lengthens by an equal amount the duration of the winter portion. The effect has a range of nearly 3° F. at Kew in the 25-year mean curve, out of a whole range of 24° F. Its magnitude at the other stations is approximately the same fraction of the whole range at those stations. It is much larger in curves for single years at Kew, but the epoch varies somewhat. It is called meteorological, as distinguished from planetary, because in the mean curves for the Continental stations Vienna and Agra it is quite different either in magnitude, or epoch, or both.

An attempt is made to account for this peculiarity by the prevalence of winds from different quarters at different times of the year. The mean temperatures of 3288 successive days (nine years) at Kew are grouped according to wind direction from eight compass points or, more strictly speaking, according to the direction at right angles to barometric gradient. The method

1 "On the Seasonal Variation of Atmospheric Temperature in the British Isles and its Relation to Wind-direction, with a Note on the Effect of Sea Temperature on the Seasonal Variation of Air Temperature." By W. N. Shaw, F.R.S., and R. Waley Cohen. Read before the Royal Society, June 20.

of reference of the temperatures is unusual. The temperature for any day is not referred to the ascertained 25-year mean for that day, but to the corresponding point of the first component in the harmonic resolution of the 25-year curve, and it is the differences from this standard which are considered. To obtain trustworthy means for the several winds the differences for each ten days of the year or for each month are grouped, and the winds are also grouped according to their average annual effect upon temperature, which is tabulated in the paper. Thus N., N.E., and E. winds (E., S.E. and S. gradients) are grouped as "cold winds," S., S.W. and W. winds as "warm," and N.W. and S.E. as "temperate."

A series of diagrams exhibits the results obtained, and it is noteworthy that the chief characteristics of the peculiarity which it is sought to explain, viz. maxima of warming effect in January and July with maxima of cooling effect in May and November, are traceable in different ways in the temperature curves for separate winds and still more markedly in those for the groups of winds. Thus the peculiarity is only partly attributable to the prevalence of warm or cold winds; part is due to a similar peculiarity in the seasonal variation of temperature of the individual winds themselves. Thus the May minimum is shown to be due partly to the special prevalence of "cold winds" and partly to the relative coldness of those winds at that season: the corresponding November minimum is attributed to the prevalence of "temperate winds" and the exceptional coldness of those winds at that period of the year. The July maximum corresponds to the exceptional warmth of the usually cold or temperate groups of winds and the January maximum corresponds especially to the frequency of occurrence of "warm winds."

The half-yearly component of the variation of temperature in individual winds remains unexplained, but the following facts are noted in connection with it: first, a similar effect is found in the temperature variation of sea-water at stations surrounding these islands and, secondly, a similar second order component with similar epoch is found in the seasonal variation of the barometric gradient between London and Valencia and still more conspicuously in the barometric gradient between London and Aberdeen.

The data as to the relation between wind, or gradient, and temperature have been obtained for Kew only.

The paper also contains an account of the variation of temperature with the type of weather prevailing, whether cyclonic or anticyclonic, and it is shown that the effect in question cannot be ascribed to the differences of frequency of these types at different seasons.

To the paper is appended a note on the effect of sea temperature upon the seasonal variation of air temperature. In this an attempt is made, by the application of the principle of the vector composition of sine curves of the same period but with different epochs, to resolve a resultant annual temperature oscillation into components corresponding to the "original oscillation" and the superposed effect of sea or land. By the application of the principle in the case of Kew, it is shown that the amplitude of the "original oscillation" at Kew cannot be less than 5·3° F. and the effect of the surrounding sea corresponds to an oscillation which cannot exceed 8·3° F. in amplitude. The resultant oscillation at Kew ought, however, to be resolved into three components—the original component, that due to the surrounding land and that due to the sea; but there are not sufficient data to determine them directly.

Application is also made of the same principles to the resolution of the temperature variation at Scilly and at a station in Siberia. The numerical results are not to be regarded as final on account of the inadequacy of the data used.

RESEARCH IN UNIVERSITY EDUCATION.

THE development of higher education in the direction of research was the keynote of the address delivered by Prof. J. G. Macgregor, F.R.S., at the University of Edinburgh on October 15, in opening the Natural Philosophy Class as the late Prof. Tait's successor. Research methods should be used in education from the Kindergarten to the University; because the spirit of self-help, of inquiry and of inventiveness which they encourage is at the foundation of all progress in science and industry. When science began to be studied in our schools and colleges about forty years ago, the schoolmen of the day followed, with few exceptions, the methods which they used in teaching the humanities. Lectures and books provided the material and examinations the test of retentivity. The system was fundamentally wrong when applied to science though sound for studies of literature. Investigation is necessary in both cases if progress is to be made, but, as Prof. Macgregor remarks, "while in science the outfit of the laboratory consists of apparatus and tools, in language it consists of the text and the lexicon."

The neglect of the spirit of research in the study of science is largely responsible for the want of public sympathy with work of investigation and the inadequacy of provision made for it. Nations like those of America and Germany which have recognised that research is not only an educational discipline but exercises a powerful influence upon industrial development, now take the initiative where we were once the leaders. Formerly, it was necessary for the young American to go to Germany to obtain the pioneer spirit, but the need no longer exists, for the leading universities of the United States have been remodelled on modern lines. In Great Britain the conservative spirit prevails and has prevented the course of university development demanded by the requirements of the age. The characteristic attitudes of the German, American and British peoples are as old as the prophets, from whom Prof. Macgregor derives an appropriate illustration.

"The German," he remarks, "may be said to have sought wisdom for her own sake as being more precious than rubies, and he is finding now that she has length of days in her right hand, and in her left riches and honour. The American, though he sought her not, heard her crying at the gates: I, Wisdom, dwell with prudence and find out knowledge of witty inventions; and having heeded her cry, he too is reaping his reward. We Britons have neither sought her for her own sake nor heeded her cry, but have said to ourselves: There is no new thing under the sun. He that increaseth knowledge increaseth sorrow, and much study is a weariness to the flesh. The sleep of the labouring man is sweet. Yet a little more sleep, a little more slumber, a little more folding of the hands in sleep. And now we fear that poverty is coming as one that travelleth, and want as an armed man."

It is the duty of those of us who are awake to national necessities to exert ourselves in the endeavour to arouse the British people to action, and our political leaders to a sense of responsibility for future welfare. More liberal provision must be made for the increase of knowledge, and men who devote themselves to research must be prized as highly as those who have contributed in other ways to the progress of the nation. There must be increase of funds and increase of freedom in the universities and the guiding principle of the work must be research. Prof. Macgregor emphasises these points in the following concluding part of his address.

Research is costly. It means increased teaching staff and adequate provision of all the requisite appliances. Much good work, it is true, may be done with a comparatively small outfit; but to obtain the best result, the outfit, if not lavish, must at any rate be generous. And as the importance of research by students has never been recognised amongst us, the present outfit is meagre.

It will perhaps occur to most of you that the princely gift of 2,000,000*l.* which Mr. Carnegie has made to the Scottish people for reducing the cost of the higher education and increasing its efficiency may be drawn upon for the present purpose, and may be sufficient. Doubtless it will be drawn upon, but it will certainly not be sufficient. When we think of the number of colleges which are to be assisted, and of the number of different departments in each, we see at once that the amount which any one department may expect to receive must be comparatively small. The moiety of the Carnegie fund which is devoted to equipment would build, equip and maintain perhaps about twenty laboratories of the more expensive kind such as are required in the various sciences and in their numerous applications. It becomes obvious, therefore, both how munificent a gift the Scottish people have received, and, since each university ought to possess many of these laboratories, how inadequate it is for the introduction of research study into the various departments of university work.

In Germany the nation itself provides for research, and does so generously, because it is, and has long been, an investigating nation. We are not; and if we introduce research into our universities it will be because, like the Americans, we have

come to recognise its educational and industrial importance. It will be individuals who will lead in this recognition; and we must therefore rely, as the Americans have done, mainly on the public spirit of citizens. The reports of the United States Commissioner of Education show that there has been in recent years a steady increase, year by year, both in the benefactions and in the Government grants which the universities and colleges have received, culminating in 1898-9 (the date of the latest report) in benefactions amounting to 4,400,000*l.* for that one year, and Government grants amounting to 1,500,000*l.*—facts which fully explain how it is that the great universities, which, of course, have been receiving the lion's share, have been able to build up, in a comparatively short time, well-equipped research schools in many departments of study. If we are to do the same, we must not rest satisfied with the equipment which the Carnegie fund can provide, but must supplement it with a liberality which, if not individually so princely as Mr. Carnegie's, will collectively exceed it in amount.

And here let me suggest that the endowment of research in Natural Philosophy in this university might well form the first instance of such enlightened liberality. Tait needs no effort of ours for the perpetuation of his name. By his scientific work he has raised for himself, as a distinguished leader in the advancement of knowledge, a more lasting monument than any that we could erect. But of his services to the University and the State there is no memorial. There are thousands of his students who have drunk from the well of his inspiration and been made stronger men by the draught. There are tens of thousands of his fellow-citizens whose pride in the Scottish metropolis has received new justification from his whole-souled devotion to its maintenance as a centre of light and leading. Is it too much to expect that they should found a research laboratory bearing his name, and thus appropriately mark their appreciation of a great Scotsman who showed by the exercise of his own creative power that Britain at least shares in the intellectual leadership of the world, and by the cultivation of creative power in his students did what he could to maintain her industrial leadership as well?

There would be little advantage in the possession of research funds, however, without full freedom to use them; and at present they could be used only to a limited extent. Research work is recognised in our universities as qualifying for certain high degrees, so high that no one is supposed to be fitted for them until five years have elapsed from the date of his having become a Master of Arts or a Bachelor of Science, so high consequently that they are taken only by the few. It is not recognised as qualifying for the M.A. and B.Sc. degrees themselves, and any time which may be spent by an undergraduate in investigation is thus condemned by our regulations to be, so far as the degree is concerned, "time elaborately thrown away." Nor is it easy to gain full freedom to teach by research; for when we ask how the recognition of research study in the undergraduate courses is to be obtained, we find that changes in regulations can be made only with the concurrence of the Scottish Universities Committee of the Privy Council, and that it is hopeless to expect the concurrence of this Committee unless it is asked for by at least two universities. It will at once be obvious that the advocate of reform has an arduous task. For he must persuade in succession his own university, a second university, and the Privy Council Committee. And this procedure is requisite, not merely to secure the desired recognition of research study, but to carry out any large measure of reform. It has obviously been devised with the object of preventing hasty and ill-considered change on the part of any of our universities, and any change whatever which does not commend itself to more than one. It may be admitted at once that it is admirably suited to the purpose; for if we think of the correspondence involved in the advocacy of any reform, the iteration and reiteration of argumentation, the button-holing, perhaps even the lobbying and "log-rolling," it becomes apparent that no better system could be devised to dampen the enthusiasm of the reformer and to perpetuate things as they are.

It is perhaps improper in one who has only recently joined your staff of teachers, and may not be fully acquainted with the advantages of the organisation referred to, to express any decided opinion about it. But, as an old student, who for years has been watching the course of his Alma Mater from afar, and is thus in a position to let you see yourselves as others see you, I may allow myself to say that the Ordinances of the Scottish Universities Commission and the authority of the Privy Council Committee seem to me to be millstones about the necks of the Scottish universities, which, unless the universities have a supernatural buoyancy, must sink them lower and lower relatively to the progressive universities of the world.

The most important condition of the steady progress of the German university has been the *Lehrfreiheit*, and the corollary insisted upon by the universities and recognised by the State, that when the best available teachers have been selected they must be supposed to know better than any external committee what is to be taught and how the teaching is to be done, and that consequently they must be free to regulate and modify their teaching as knowledge advances and as methods are improved.

And, similarly, one essential condition of the progress of the American university has been its autonomy. Johns Hopkins University, non-existent twenty-five years ago, is to-day one of the leading universities of the world, because it put at its head a talented educational reformer and gave him a free hand; and in consequence of a similar policy, Harvard, in the last quarter of a century, has been transformed from being a leading American university to being a leading world's university. These two great institutions work on quite different lines. Had either required to persuade the other of the value of its organisation and then to persuade a Committee of Congress, it is safe to assert that the extraordinary development which both have exhibited would never have occurred.

The question of the relation of the universities to the Privy Council Committee, of the advantages of individual as opposed to collective development, of the kinds of change which ought to be capable of being made from within, and the kinds which ought to be submitted to an external tribunal—these are questions of too great complexity to be discussed in the last paragraphs of an address. But when the introduction of research work into the undergraduate courses is found to be among the reforms which must wait for collective action and the consent of an external body, it becomes obvious, I think, that the line between changes which may be made from within and changes which require approval from without has been so drawn as to hamper unduly the development of our universities, and that it requires to be redrawn in the spirit of progress.

Meantime, as to the particular change which I am advocating to-day, we need not despair. Reform in this direction is in the air. Under the stress of the national industrial crisis and the growing conviction that something must be wrong in our educational system, those educationists who have long advocated it are securing to-day an attention such as they have never before received. And when we find the Chancellor of the University of Birmingham, a leading Cabinet Minister, eager to introduce research into his university, and the chairman of the Educational Section of the British Association, our Minister of Education, as eager to introduce it into his schools, we are encouraged to hope that at no distant date the movement may be fully developed which was inaugurated in this university through the profound educational insight of Prof. Tait, and that all our universities may be enabled to exert the stimulating influence that schools of the higher education should do, not merely on industrial development, but on all forms of progressive activity.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Financial Board has published a proposal that the University should purchase some six acres of land belonging to Downing College, and adjoining the new buildings for geology and botany. The site is practically the only one now available for the extension of the museums, and it will, if not secured by the University, be divided up by new streets for ordinary building purposes. The price is about 25,000*l.*, which, in the absence of benefactions, will have to be raised by loan.

Dr. Anningson, Dr. Collingridge, Prof. Woodhead, Mr. J. E. Purvis and Dr. Tatham have been appointed University examiners in sanitary science.

At a meeting held under the auspices of the Philosophical Society on November 18, it was decided to invite the British Association to visit Cambridge in 1904 or 1905.

MR. CARNEGIE has announced that he will give 400,000*l.* more to Pittsburg, half to the Carnegie Institute and half to the new technical school, the building of which will shortly be commenced.

FROM the Report of the Somerset County Education Committee we learn that an experimental farm has been established under the auspices of the committee at Bickenhall, near Taunton, where systematic observations are made and experiments conducted on the breeding, feeding and produce of farm animals, more especially those usually found on a dairy farm. Experiments are also made on the production of various crops.

THE annual meeting of the Association of Headmasters of Higher Grade Schools and Schools of Science was held on Friday last at the rooms of the Society of Arts. Mr. E. J. Cox, Headmaster of the George Dixon Higher Grade School, Birmingham, delivered his presidential address, taking for his subject the recent return of the Board of Education, which gives statistics relating to schools of science in connection with board schools and certain conclusions which have been drawn from the return by a section of the Press. Mr. Cox, and the association over which he presides, maintain that these schools of science are providing a thorough and suitable preparation for boys who will later proceed to workshops and factories. Judging by the remarkable unanimity of the reports of the inspectors of the Board of Education, South Kensington, it may certainly be said that these schools provide the best preparation for the later work of the technical school to be obtained in this country. It is to be hoped that future legislation will provide a place in the national system of education for schools of this character, since they effectually ensure that the brightest children of the elementary schools shall receive practical instruction in the methods of science. It is a hopeful sign for the future of English education that several representatives of different trade societies were present at the meeting and showed by their speeches that they understood the value of a knowledge of science to all engaged in manufacture.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Astronomical Society, November 8.—Dr. J. W. L. Glaisher, president, in the chair.—Mr. S. A. Saunder read a paper on the determination of selenographic positions and the measurement of lunar photographs. This was a second paper on the subject, dealing with the determination of a first group of standard points on the moon, by measures made at the telescope and on photographs. Prof. Turner said this was a work in which those could assist who possessed telescopes of moderate aperture, as it had been found that very large apertures were unsuited for measures of the lunar surface.—Father Sidgreaves read a paper on the spectrum of Nova Persei from February 28 to April 26; with an appendix, dealing with its spectrum in August and September. Photographs were shown of the spectrum taken at Stonyhurst on August 27 and September 5, when it had become a bright-line spectrum, some of the lines remaining very broad and well defined.—Mr. A. R. Hinks gave an account of the experimental reduction of some photographs of Eros made at Cambridge Observatory for the determination of solar parallax; he explained the methods employed and gave some preliminary results.—Mr. H. C. Plummer read a paper on periodic orbits in the neighbourhood of centres of libration.—Mr. Bellamy read his paper on the place of the variable star RU Herculis and the neighbouring stars from photographic measures.—Prof. W. W. Campbell, Prof. J. Scheiner and M. Ch. Trépied were elected associates of the Society.

Linnean Society, November 7.—Prof. S. H. Vines, F.R.S., president, in the chair.—Mr. W. Botting Hemsley, F.R.S., on behalf of the Director of the Royal Gardens, Kew, exhibited the following specimens:—(1) A West Australian umbelliferous shrub, *Siebera deflexa*, which produces tubers, called *Yuke* by the aborigines, who eat them both raw and cooked. Many shrubs in dry countries form large tuberous stocks from which annual stems spring; but the tubers of *Siebera deflexa* grow in strings showing no trace of eyes or buds, but scars where stems may have been detached. Whether independent plants spring from the separate tubers is a question which remains to be determined. (2) Germinating seeds of *Araucaria Bidwillii*, received from Grahamstown. The peculiarity in the germination is that there are two distinct stages; in the first stage the radicle emerges from the shell of the seed, eventually bringing out the petioles of the cotyledons and the axis of the plantlet. The radicle grows into a carrot-shaped woody body, from which the petioles of the cotyledons disarticulate, leaving a few minute rudimentary leaves forming the point of the plumule. After some weeks the second stage begins with the elongation of the plumule, which eventually becomes the trunk of the tree. It appears that the second stage may be delayed a considerable time without loss of vitality. The germination of the seeds of *Araucaria Bidwillii* had been previously observed, and the process has been described and illustrated in Regel's "Gartenflora," 1865, p. 103; but the two stages of growth escaped notice. Another peculiarity is there pointed out: each seed contained two or more embryos, which germinated and grew so that 164 plants were raised from seventy-five seeds. *Araucaria Bidwillii* is the *Bunya-bunya* of Queensland, and the seeds were formerly an important article of food of the Australian aborigines. (3) A drawing of *Archidendron solomonensis*, a new pluricarpellary leguminous tree, native of the Solomon Islands, where it was discovered by Archdeacon Comins. In this instance there were three ripe pods developed from one flower; and it was explained that in the flowering stage there were usually eight carpels; but they probably rarely, if ever, all reach maturity. The genus Archidendron was founded on an Australian species, and since then several other species have been discovered in New Guinea and the adjacent islands. (4) A selection of South African species of Helichrysum showing the great diversity in habit, foliage and flowers displayed by this very large genus of Compositæ.—Dr. Rendle showed germinating seeds of *Crinum longifolium*, received from Mr. E. A. Bowles, as an example of the so-called bulbiform seeds which characterise this and some other allied genera of Amaryllideæ.—The president directed attention to a specimen of *Luzula nivea* from a cultivated plant of unusual dimensions.—Mr. Cecil Warburton, on behalf of Miss Alice Embleton and himself, read a paper on the life-history of the black currant gall-mite, *Eriophyes* (*Phytoptus*) *ribis*, hitherto very imperfectly known, and dealt particularly with its behaviour during the migration-period, which lasted from the middle of May to the middle of June. Its natural enemies and its relation to the red currant plant were also discussed.—Mr. C. B. Clarke, F.R.S., communicated some notes on the types of species of Carex in Boott's Herbarium.

CAMBRIDGE.

Philosophical Society, October 28.—Mr. J. Larmor, vice-president, in the chair.—Prof. A. Macalister was elected president for the session 1901–2.—Notes on minerals from the Lengenbach Binnenthal, with an analysis by Mr. H. Jackson, by Mr. R. H. Solly (see vol. lxiv. p. 577, October 10).—Some remarks on the notion of number, by Dr. Hobson.—The Hall effect in gases at low pressures, by Mr. H. A. Wilson. The experiments described in this paper were undertaken with the object of detecting and investigating the Hall effect in the positive column of the ordinary electric discharge at low pressures. A vacuum tube was constructed having two small electrodes 6·5 millimetres apart, attached to a stopper ground into a side tube, joined on at right angles to the main discharge tube. By rotating the stopper the two small electrodes could be made to lie both in the same equipotential surface of the positive column. The difference of potential between these electrodes was measured by means of a quadrant electrometer, and the stopper was turned until the electrometer deflection was zero. A magnetic field was then applied perpendicular to the line joining the two small electrodes and to the direction of the discharge. It was found that the field produced a difference of potential between the small electrodes which appeared to be a true Hall effect and was proportional to the magnetic field. In the uniform positive column this transverse potential gradient was found to be nearly independent of the current through the tube and inversely proportional to the pressure of the air in the tube. At 1 millimetre pressure the difference between the velocities of the negative and positive ions due to one volt per cm. was found to be $14 \times 10^4 \frac{\text{cms.}}{\text{sec.}}$.—On some problems in electric convection, by Mr. G. T. Walker. The paper deals with problems involving the motion of electrified particles through dielectrics which are themselves in motion relative to the ether. It is shown that if space on one side of an infinite plane be occupied by a dielectric and this medium be moving at righ angles to its bounding plane, the determination of the electric and magnetic forces due to a point-charge possessed of a velocity

in the same direction can be effected: the images are moving point-charges. Attention is drawn to the inequality of the action and reaction in some of these cases, and the results are shown to be consistent with expressions obtained for the energy of the field.—On some phenomena connected with the combination of hydrogen and chlorine under the influence of light, by Mr. P. V. Bevan. When light of sufficient intensity acts on a mixture of hydrogen and chlorine in equal proportions the first effect observed is an increase in the volume of the mixture. This is shown to be due to a rise in temperature caused by the heat evolved in the formation of hydrochloric acid. It is also shown that the fall in temperature of the gas mixture to that of the surrounding medium accounts for the observed decrease in volume after light ceases to act on the mixture.

MANCHESTER.

Literary and Philosophical Society, November 12.—Mr. Charles Bailey, president, in the chair.—Mr. W. B. Faraday showed a stone adze, one of several similar implements which have been found, from time to time, near Leek. He suggested a comparison with the Eolithic stone implements which were recently shown to the Society by Mr. R. D. Darbyshire.—Dr. Charles H. Lees described the Hampson air-liquefying apparatus presented to the physical laboratories of the Owens College by Sir Henry E. Roscoe. After explaining the principle on which the action of the apparatus depends, and describing the experiments of Joule and Thomson which led to the discovery of that principle, Dr. Lees gave a *résumé* of the present state of knowledge of the properties of liquid air and of other bodies when cooled down to the temperature of liquid air.

PARIS.

Academy of Sciences, November 11.—M. Bouquet de la Grye in the chair.—Extract from a letter of M. Jansson, noting the successful results of the eclipse expedition at Cairo (see p. 62).—On a new method of manipulating liquefied gas in sealed tubes, by M. Henri Moissan. Since solid carbonic acid can now be readily obtained, experiments were made with various liquids as solvents to see what temperatures could be reached, the evaporation being increased by a current of dry air. Of the liquids tried, methyl and ethyl alcohols, methyl chloride, aldehyde, acetic ether and acetone, the last named proved to be the best, a temperature of $-98°$ C. being obtained by its means. If the current of dry air is previously cooled to $-80°$, the second mixture of acetone and carbon dioxide reaches $-110°$ C. Details are then given of the best method of storing pure gases in the liquid form in sealed tubes, and of the precautions necessary.—On the action of the metal ammoniums upon hydrogen sulphide, by M. Henri Moissan. At a temperature between $-75°$ and $-70°$ liquid sulphuretted hydrogen reacts upon lithium-ammonium, giving a sulphide of lithium-ammonia and free hydrogen. The molecule $(NH_4)_n$, if it is produced in this reaction, is not stable at this low temperature and splits up into ammonia and hydrogen. The reaction with calcium-ammonium is similar.—On the origin of the starch in the grain of wheat, by MM. P. P. Dehérain and C. Dupont.—On the absence of electric displacement during the movement of a mass of air in a magnetic field, by M. R. Blondlot. The experiments described were undertaken with a view of deciding between two opposed theories. It was found that in air there is no displacement; this is contrary to the theory of Hertz on the electrodynamics of bodies in motion, but is in agreement with the theory of H. A. Lorentz.—On rational differential equations, by M. Edmond Maillet.—On the number of roots common to several equations, by M. A. Davidoglou.—A new method for the study of microphonic currents, by M. A. Blondel. The amplitude of the oscillations is increased by a suitable resonator, and a bifilar oscillograph used giving deviations of several millimetres for one milliampere. A diagram of the curves obtained with the five vowels accompanies the paper.—On the formation of ozone, by M. A. Chassy. A given volume of oxygen was submitted in an ozoniser to a current of known intensity. It was found that the law of increase of ozone was the same whatever the intensity of the electric current. A feeble current always produced the same effect as an intense current, provided that it acted over a time sufficiently long, or that the flow of the gas was sufficiently slow.—The application to man of the regeneration of confined air by means of sodium peroxide, by MM. A. Desgrez and V. Balthazard. A description of the improvements in detail of an apparatus previously described.

PUBLIC HEALTH ADMINISTRATION IN AMERICA.

Municipal Sanitation in the United States. By Chas. V. Chapin, M.D., Superintendent of Health of the City of Providence. Pp. viii + 970. (Providence, R.I.: Snow and Farnham, The Providence Press, 1901.)

THIS work is not a treatise on the principles of sanitation, and, in fact, these principles are rarely referred to; it is rather a compendium of sanitary practice in the United States of America. The author devotes but little space to an expression of his own views, but his opinions whenever given are such as will meet with very general approval. In the introduction he states that the preparation of the present volume was primarily undertaken to meet his personal needs. An investigation along several lines of public health work suggested the utility of a comprehensive study of sanitary methods, and, as a consequence, this volume was prepared, in the hope that the material gathered together will prove as useful to other health officers as it has to the author.

The work is designed for American readers, but much of it will prove interesting and suggestive reading to those who have to do with sanitary administration in this country. The points which will perhaps strike the British reader most are: The extent to which the sanitary law or procedure may vary in different States; the scope and stringency of certain sanitary regulations; and the frequent paucity of efficient machinery to see that the law is observed. It is comparatively easy to frame an almost ideal set of sanitary statutes and regulations, but it is a very difficult matter to enforce them thoroughly, and it is evident that sanitary administration does not always keep pace with sanitary legislation in the United States. The average of all those cities of America, given in a rather long table on pp. 128 and 129 of the work, show the population for one inspector to be about 30,000; but in Providence there is only one to every 87,000 of population. A great many health officers, we are informed, receive no compensation at all, but serve their fellow-citizens simply from public spirit; thus in Minnesota in 1898, of 214 health officers, 83 received no pay, and one of these was in "a city of 5000 inhabitants." In villages, towns and cities of small or moderate size, the health officer is expected to do nearly all the sanitary work of the community. He acts as the secretary to the Board of Health, and attends personally to communicable disease, attaching placards, giving instructions and often doing the disinfection himself. He also investigates nuisances and often serves notices for abatement. As a general rule, the scale of pay to the health officers is very similar to that in Great Britain. It is, moreover, very generally the custom in cities, often of moderate size, for the health officer to be entrusted with the duty of collecting and recording the deaths in the population.

In America, boards of health, which are now established in all the States except Georgia, Idaho, Montana, Oregon and Wyoming, are given more or less legislative and executive authority in matters which experience has shown they can best control, but as a rule the State Board of Health is considered chiefly as an advisory board. In many cases the State reserves to its State Board of Health executive powers in matters of quarantine, the control of communicable disease and diseases of animals, the adulteration of food, &c.; and the State Board of Health in Massachusetts has, in addition, set an example in the work of investigation which it will be difficult for others to equal, and that Board's extensive experiments upon water and sewage purification are highly valued by sanitarians in this country. The principles of local self-government in sanitary as in other affairs is in the main recognised and adhered to. Outside of municipalities the sanitary organisation, usually in the form of boards of health, may be established either in townships or counties. Of the thirty-six States, twenty have provided for a county form of sanitary government, and sixteen have a township form of sanitary government.

Reference may here be made to a few matters of public health administration in the United States which are of special interest to British readers. The use of preservative in milk or cream is altogether forbidden in some States, and several State and municipal standards for milk require 3·5 per cent. of fat and 9 per cent. of solids non-fat—a higher standard than that which obtains in this country; and in the city of New York, condensed milk must contain fat to the amount of 25 per cent. of the milk solids. A few States (New York, &c.) require the application of the tuberculin test to cows kept in the city, and many States now attempt to secure the destruction of herds most affected with tubercle and to help farmers to free their herds from tuberculous animals. How much they have really accomplished in this direction is not entirely clear, but it does not appear to be great. Considerable opposition is experienced, and little is done save on the application of the owners themselves.

In most communities a placard or sign is put upon the infected premises to notify the public of the presence of infectious disease. Laws requiring the vaccination of school children have been declared constitutional in Indiana, Pennsylvania, New York and California; sometimes it is the teacher who is required by the statute to enforce the law, by excluding the unvaccinated; more often, however, it is the school board or school committee who are supposed to have full control of the teachers. Garbage (animal and vegetable matters from dwellings, shops, markets, &c.) is rarely removed less often than once a week, but in Washington it is removed *seven* times a week; in New York, Philadelphia and some other towns, *six* times; and six times weekly in the summer months of the year in many other instances. The dry refuse (ashes and rubbish) is not usually quite so frequently removed; the work is done in New York and Brooklyn *six* times a week, and in many cities two or three times a week, but in most communities the interval between removals is one week.

There is little doubt that more than one-half of the water furnished in the United States is wasted, for the *per capita* consumption in American is twice as great as that in European cities, and in the few American cities which are metered the *per capita* consumption is not one-half what it is in the unmetered cities. It appears to be the experience in America that meters diminish waste, but do not

E

limit the legitimate use of water. In many States and cities either the ice is inspected or the source from which it is obtained, or the local sanitary authority controls its cutting or sale.

Spitting on the floor of public conveyances or on the side-walks—a dirty habit which creates a nuisance and favours the spread of tuberculosis—is prohibited by regulations which have been very generally adopted. It has, however, been found insufficient to forbid spitting on the floor of conveyances, as it is said that persons seeing such a rule have deliberately spat upon some other portion of the conveyance. A recent State definition of a nuisance (Utah, 1899) is very commendable. A nuisance is "whatever is dangerous to human life or health, and whatever renders soil, air or water impure and unwholesome." The Board of Health of Boston adopted regulations in 1900 for control of the barbers' trade; *inter alia*, mugs, shaving brushes and razors must be immersed in boiling water after every separate use thereof; alum, &c., used to stop the flow of blood, must be so used only in powder form and applied on a towel; the use of powder-puffs and sponges is prohibited; and every barber must cleanse his hands thoroughly immediately after serving each customer. These refinements of sanitation must be very difficult to enforce.

There are excellent reasons why the care of the sick poor should be a part of health department work, and the care of these is in a number of States wholly or partially in the charge of the health department. In most cases it is the outdoor or dispensary work which is given to the health department, but in rarer instances that department also manages the public general hospitals.

The sweating system is said to be associated with, if it be not the direct cause of, the most terrible phase of human life that is to be found in the United States. The "sweat-shop" is a manufactory in the dwellings of the very poor, among whom, if the home be healthy, the labour reasonable and the wages fair, such work is by no means to be discouraged; but the conditions of labour are often such as lead to the destruction of the home by the overcrowding and intense application and competition and the starvation wages of the sweating system. American legislation fails, like our own, to bring about any sufficient amelioration of the disease and misery entailed by the sweating system.

In conclusion, reference may be made to a very useful and full appendix of handbills, forms, notices, &c., used by different sanitary authorities in the United States, which adds much to the value of an interesting and important work.

THE CORRESPONDENCE OF HUYGENS.

Oeuvres complètes de Christiaan Huygens. Publiées par la Société Hollandaise des Sciences. Tome neuvième, Correspondance 1685–1690. Pp. 663 + 3 plates. (La Haye: M. Nijhoff, 1901.)

THE monumental edition of Huygens' works has now reached its ninth volume, and at least one more will be required to complete his voluminous correspondence. When reviewing previous volumes we remarked that many private letters of a non-scientific nature might well have been omitted, as their insertion is the principal cause of the great extent to which the work has grown; but this complaint does not apply to the volume now before us, in which there are scarcely any letters which one could wish omitted, as the few which do not treat of scientific matters give interesting glimpses of life and manners.

In the beginning of 1685 Huygens was still negotiating with the French Government about his return to Paris, and it is not quite clear whether he wanted to go back or not, and whether the revocation of the edict of Nantes was really the sole obstacle. Anyhow, nothing came of the correspondence, and he stayed on at The Hague till the spring of 1688, when he settled at Hofwijck, a property in the neighbourhood of the city which had belonged to his father (who died in March 1687) and of which his elder brother, Constantyn, lent him the use. As Constantyn was secretary to the Prince of Orange, his time was naturally much taken up with affairs of State, but he still found time to correspond with his brother on his favourite pursuit of telescope making, until he had to accompany William III. on his memorable expedition to England in 1688. Several letters give vivid pictures of the great anxiety felt in Holland after the departure of the fleet and the surprise and joy at the rapid progress of the Prince from Torbay to London. The interesting news contained in the letters of Constantyn from London inspired Huygens in the summer of 1689 with a wish to renew old acquaintances and make new ones in England, and accordingly he spent more than two months there, associating with Boyle, Halley, Newton (whom he now met for the first time), his old correspondent Duillier and others. The greatest scientific event of the time was, of course, the publication of Newton's "Principia" two years before. In June 1687 Duillier wrote to Huygens from London that some of the Fellows of the Royal Society were much excited over the approaching publication of a new work by Newton, and mentioned shortly some of the subjects dealt with in it. In reply, Huygens wrote that he was longing to see the book and did not object to the author not being a Cartesian, provided he did not make such an assumption as that of universal attraction. No doubt he and Newton must have had some conversations on the subject in 1689, and two memoranda by Newton on motion in a resisting medium probably date from this visit of Huygens to London. They were already published in 1701 together with a few notes written by Huygens in his copy of the "Principia," which after his death was acquired by a certain Groening, who imagined that Newton's memoranda (which are in his own handwriting) were also written by Huygens. In the "Discours de la Cause de la Pesanteur," published in 1690 with the "Traité de la Lumière," Huygens proves the earth to be an oblate spheroid and explains why the seconds' pendulum is of different length in different latitudes. But he assumes that gravity has its seat at the centre of the earth only, and in the appendix (written after the publication of the "Principia") he refuses to admit that all the particles of two or several bodies attract or tend to approach each other, as it seems clear to him that such attraction cannot be explained by any principle of mechanics. And in a letter to Leibnitz in

the same year he says that he often wonders how Newton could take the trouble to make so many researches and difficult calculations which have no foundation but this principle of universal attraction, which seems to him an absurd one.

With Leibnitz, Huygens was in fairly constant correspondence during the year 1690, chiefly on the subject of the differential and integral calculus, to which Leibnitz invited his attention; these letters have already been published more than once, but are here illustrated by several extracts from the notebooks of Huygens. After the publication of the "Traité de la Lumière" in 1690 (written in Paris twelve years earlier), Leibnitz wrote to express his surprise at, and satisfaction with, the undulatory theory, adding that when he saw how well it accounted for double refraction he passed from esteem to admiration. Papin also wrote to express his general approval, but otherwise there are very few allusions in the correspondence to the wonderful theory of Huygens, which had to lie dormant for more than a century before it even began to be seriously examined and to gain adherents. It is very curious that Newton should reject the undulatory theory of light while Huygens refused to accept the theory of universal gravitation, on both of which theories our modern natural philosophy is founded. But while the objections of Huygens did not retard the progress of the theory of gravitation, Newton's rival theory of light is certainly responsible for the long neglect of the true theory set forth by his Dutch contemporary.

Among the subjects which throughout Huygens' life continued to occupy his mind the improvement of clocks held one of the foremost places, and he never ceased to hope that in this way the important problem of finding the longitude at sea might be solved. Already, in 1662, he had his clocks tried at sea on a voyage from The Hague to London, but the attempt was a complete failure. Although he had in the meantime made the important invention of spiral-spring balances, he felt that even with this essential improvement no watch was to be trusted on a long voyage owing to the great influence of changes of temperature on the rate, and he therefore determined to try his pendulum clocks again at sea. In 1685 he cruised in the Zuyder Zee with two clocks suspended from the ceiling of the cabin in gimbals, and though the sea was very rough one of the clocks kept going the whole time. Encouraged by this success and being assured that the motion of a large ship would be far less violent than that which one of the clocks had been able to withstand, he had the experiment repeated in the following year in a ship belonging to the Dutch East India Company on a voyage to the Cape, giving the captain very detailed instructions as to the management and rating of the clocks. On the return of the *Alcmaer* in 1687 he learned that the clocks had kept going, though not as regularly as he had hoped. Huygens sent a lengthy report to the Company, with a large chart (reproduced in this volume) showing the track of the ship, first as estimated by the pilots, then as calculated by means of the clocks (passing right across Ireland and far to the east of the first one), and finally the same "allowing for the centrifugal force of the earth." This last track agrees fairly well with that laid down by the pilots. The matter was not lost sight of in the following years, notwithstanding the many other occupations of Huygens, and at the end of the volume we find again a number of letters exchanged between him and Graaf, who had brought the *Alcmaer* home from the Cape and who was then about to try the experiment again in another ship. But a great many years were to pass before Harrison solved the problem in quite a different manner.

It is impossible to read this splendid edition of Huygens' correspondence without being struck with the great care bestowed by the editors on their work. Throughout the volumes every allusion to persons, to contemporary events or to scientific matters is explained and commented on in footnotes, often of considerable length, which form a most valuable adjunct to the work. At the head of each letter it is stated where the original is to be found, whether it has been previously printed, and what letter it is in reply to or which one contains the reply to it. Future historians of the science of the seventeenth century will, indeed, have cause to thank the Haarlem Society of Science and especially the editors to whom this national undertaking has been confided.

In addition to the chart already mentioned, the volume contains a plate with views and plans of Hofwijck, where Huygens spent the last seven years of his life, and as frontispiece a fine portrait of the elder Constantyn Huygens from a drawing by his great son.

J. L. E. D.

ELEMENTARY BOTANY.

A Laboratory Course in Plant Physiology. By William F. Ganong, Ph.D. Pp. vi + 147. (New York: Holt and Co., 1901.)

Methods in Plant Histology. By Charles J. Chamberlain, Ph.D. Pp. viii + 159. (Chicago: University Press, 1901.)

First Studies of Plant Life. By Geo. Francis Atkinson, Ph.B. Pp. xii + 266. (Boston, U.S.A.: Ginn and Co., 1901.) Price 2*s.* 6*d.*

DR. GANONG seems to us to express sound views on the teaching of science in general and of plant physiology in particular, and the remarks on pp. 9 and 10 of his introduction might well be taken to heart by teachers; the same observation applies to his section on "Teaching and Learning," and careful consideration of the rest of this interesting manual convinces us that the author has much of the spirit of the true teacher in him. In other words, he has a share of that genius which calls forth from his students the desire to do something more than merely gather the opinions and statements of others as to the meaning of all those movements, exchanges of matter, increases in size and alterations in volume, &c., which constitute life.

It seems to us that a student who conscientiously works through the subject of this book, in the manner inculcated by the text and imbued with the spirit of inquiry manifested by the author, must learn much that is worth learning, both on account of its value as knowledge of the ways of living plants and on account of its significance in philosophy.

The experiments are as a rule simple, to the point, and

adequately but not over described; while the results, instead of being merely set forth by the teacher, have to be looked for and thought about by the student himself.

Faults there are, and probably must be in such a book, and we could criticise somewhat severely the meagre plan of a physiological laboratory submitted on pp. 29-30, and the outline course of study of structure and of the properties of protoplasm; but against these deficiencies may fairly be set some neat suggestions and devices, as, for example, those on comparative polygons (p. 15) and for experiments on germination, root-pressure, geotropism, &c. We do not like such terms or expressions as "borrowable" (p. 58), "diagramming" (p. 75), "other tropisms" (p. 132), and quite fail to understand how it can be said (p. 135) of locomotion that it is "almost purely ecological, with but a slight basis in pure physiology."

Nor can we pass over the following without protest: "5. What is the chemical composition of living protoplasm?" (p. 52). It is obvious on reflection that we know nothing of the chemical composition of *living* protoplasm.

We are also struck with the untidy appearance of some of the experiments—*e.g.* Fig. 13—though not all.

The information (pp. 71-72) regarding nutritive solutions, and (p. 100) water cultures is too meagre; and to say of absorption (of lithium citrate) "But perhaps such absorption is too obvious to need special experiment" is a flagrant departure from the excellent principles inculcated elsewhere.

On the other hand, surely the following precaution with the clinostat is of the order of trivialities: "The clock will need winding once in two days, and while the cork is removed for the purpose, it should be kept slowly revolving in the hands" (p. 121).

A clearly written, excellently printed and compact little handbook for the beginner in laboratory practice has long been wanted, and Dr. Chamberlain's volume comes nearer to satisfying the want than many. But it has, in our opinion, one fundamental drawback which would spoil its claims to be—what it might have been—*the* elementary laboratory book of methods for botanists, namely, in attempting to be both a guide to laboratory methods and a handbook of exercises in plant-histology, each of its double functions being too incomplete in treatment. For instance, the meagre description of the paraffin bath on p. 4 should either be clearer or omitted altogether, and the practical value of the curious formulæ for alcohols on p. 9 seems to us not obvious. On the other hand, the recommendation to inoculate a mouse with *Anthrax* (p. 76) can hardly apply to an elementary student, and several of the studies—*e.g.* of *Xylaria* (p. 83), *Marsilea* (p. 111), &c.—seem to us both unsuitable and inadequate in treatment. The poor photographic figures of nuclei in *Lilium* are also unnecessary.

In spite of these criticisms the first half of the book contains many useful hints on methods, and we should like to see it expanded, to the ultimate exclusion of the second half.

Dr. Atkinson's little book has a wealth of excellent illustrations and some ideas of value to the teacher and student of purely elementary botany or "Nature study," but it only brings out once more the clear issue that all such teaching depends for its efficiency on the genius of the individual teacher. In the right hands, Chapters xv.-xvii., for instance, dealing with the formation of starch in the living plant, will assume delightful aspects. We do not doubt that this would be the case in the hands of the author, but even his simple style and ingenious illustrations show only the more clearly that all depends on the personality of the teacher in these fundamental matters. The section on "Battles of Plants in the World" is excellent reading, but we doubt if children could be made to appreciate the subject except in the open air and in the company of the ideal teacher, who is rarely or never present with the book.

TRUTH AND ERROR IN VON KÖLLIKER.

A. von Kölliker's Stellung zur Descendenzlehre. Ein Beitrag zur Geschichte moderner Naturphilosophie. Von Dr. Remigius Stölzle. Pp. 172. (Aschendorffsche Buchhandlung, Münster i. W., 1901). Price Mk. 2.

DR. REMIGIUS STÖLZLE, professor of philosophy in the University of Würzburg, has paid his illustrious scientific colleague A. von Kölliker a great compliment. He has dissected Kölliker's works, and separated the wheat from the chaff, as he did not long ago in the case of Karl Ernst von Baer. The analysis of nine important works, from an article on Darwinism in 1864 to the veteran's interesting "Erinnerungen" in 1899, is careful and scholarly, and the critical exposition is arranged so clearly that the reader can find out at once what Kölliker thought about variation, heredity, natural selection, or the like. While the author has very strong convictions, he expresses these with a dignified restraint, and says nothing harder against naturalists than that it is a pity to be too busy to take advantage of philosophical discipline. For those who are fond of argument the book will serve as an interesting introduction to the problems of organic evolution.

Prof. A. von Kölliker's contributions to biology—through more than half a century—have been many and varied; indeed, the magnitude of his work, alike in quantity and quality, is a lasting example to the spirit of research; and, though it is difficult always to read with patience, Stölzle's detection of "fundamental errors" is really part of a tribute to the anatomist's greatness. Is not criticism, after all, the sincerest form of flattery? But there is, by the way, a lack of discernment or of the sense of humour in placing Profs. Fleischmann and Weismann side by side among those who are responsible for recent "Angriffe oder Verdikte" on Darwinism.

The first great error is a purely mechanical interpretation of nature, the second is a denial of purposive principles, and the third is an evolution theory which is said to leave no *rôle* for the Creator. In evidence of these hateful heresies there is no lack of citation of chapter and verse; nor is it to be supposed that the author simply *calls* them "Irrgänge des Denkens"; he seeks to substantiate his accusations, and to those who agree with him the case will doubtless appear convincing.

But there is a brighter side to the picture; there is truth as well as error in the writings of Albrecht von Kölliker. Of permanent truth (von bleibender Wahrheit)

is his critique of Darwinism; it has stood the test of time and is now admitted as justified, "and Darwinism, for scientific circles at least, is at its last gasp. Weismann, the toughest champion of Darwinism, can now write over all his works devoted to the rescue of the selection-principle, '*In vanum laboravimus.*'" These are brave words, but the game is "bluff."

A second "permanent truth" expressed by von Kölliker was that organic evolution can only have come about through internal factors, for von Kölliker is one of the many who have groped after "an unknown factor," a "phyletische Lebenskraft." It has often seemed like a clue, this idea of an internal tendency to progress, but it has not as yet led us anywhere; and we relapse from obscure talk about "bathmism" into an ætiology like Topsy's "specks I growed." There may be some with the bad taste to prefer Weismann's "germinal selection."

A third "permanent truth" in von Kölliker's position is that "he regarded all theories of descent, including his own, as having only the status of probabilities," and this is to appraise them rightly. In other words, evolution-theories were to him, as to most clear-headed people, simply conceptual formulæ more or less justified by their success in fitting the facts. Here, at least, those who regard von Kölliker's heresies as expressive of a useful scientific method and those who denounce them as errors of judgment, those who stand by the selection-idea and those who think that it has been literally worked to death, may find a provisional peace, until they begin again to try if they cannot get "any forrarder."

J. A. T.

OUR BOOK SHELF.

A Treatise on Medical Jurisprudence. By G. V. Poore, M.D., F.R.C.P., Professor of the Principles and Practice of Medicine, University College, London. Pp. xxiv+533. Eighteen illustrations. (London: John Murray, 1901.)

THE book before us consists essentially of a series of lectures delivered by Dr. Poore at University College during the time when he occupied the chair of medical jurisprudence in that institution; now that he has passed to another sphere of duties, it is well that his labours as a teacher of this most important subject should endure in the concrete form of a manual. The lectures have been freely edited by himself, and doubtless touched up by others, but in spite of this they remain still essentially lectures, delivered in a pleasant colloquial style; if from the point of view of highly systematised contents, something by this method has been lost, something has also been gained, in that the volume before us may certainly be designated one of the most readable which it has ever fallen to our lot to peruse.

To turn from the manner of the book to its matter, it is quite impossible in a short notice to do adequate justice to the mass of fact which it contains. The book is not very fully indexed, and to get an adequate idea of its contents the table of contents itself must be read. This consists of a series of detailed chapter headings which are repeated throughout the book at each chapter.

Inter alia we would draw special attention to Chapter ii., which deals with the legal relations of the medical profession. The subject-matter of this chapter, as in many others throughout the book, is elucidated by illustrative cases culled from the records of the Law Courts. Amongst these cases we may mention the Tichborne, Palmer, Lamson and Maybrick cases, each of which is fully described under the subject which renders them of permanent interest to the medical jurist. With regard to the toxicological part of the subject, the author adopts the wise method of only dealing with the symptoms produced by, and the detection of, those poisons which have actually been used criminally. An interesting chapter on food-poisoning is, we venture to think, not strictly within the scope of the work. The criminal of to-day is perhaps turning his attention to ptomaines, and it may be that the criminal of the near future will actually employ them. It is only to be hoped that modern chemistry will be equal to the task of their identification. A very useful chapter for the medical practitioner is the one upon insanity, and the one immediately following, upon the legal relations of the insane. In these two chapters he will find full information with regard to what is very often a puzzling subject, viz. what to do and how to do it when one is suddenly called to a case which obviously requires restraint. Is it to be wondered at that the busy medical man has sometimes to be censured for not complying with the law when, as Dr. Poore tersely puts it, the law in question contains more than three hundred sections and clauses, and weighs half a pound?

The volume concludes with eleven appendices upon various subjects of importance to medical jurists. Amongst these may be mentioned a most interesting appendix (illustrated) by Dr. J. G. Garson upon "The metric and finger-print identification of criminals as carried out at New Scotland Yard."

We may close our remarks by saying that Dr. Poore's book deserves, and will surely have, a very wide circulation, supplementing rather than replacing the more systematised and voluminous works upon this subject.

F. W. T.

Ueber Museen des Ostens der Vereinigten Staaten von Amerika; Reisestudien. By A. B. Meyer. Part ii. Illustrated. (Berlin, 1901.)

IN this fasciculus the learned Director of the Royal Zoological and Ethnographical Museum of Dresden concludes his interesting account of the museums and libraries of the United States visited during his recent tour. Here we may avail ourselves of the opportunity of correcting a misrepresentation of the author's opinions which unfortunately occurs in our notice of the first portion of his work. Instead of stating that Americans are ahead of us in the matter of museum fittings, Dr. Meyer awards the preeminence in this respect to European institutions, although he is fain to confess that as regards libraries and library installations we are not abreast of America.

In the present part Dr. Meyer discusses the chief public institutions of Chicago connected with art, literature and science, namely, the Field Columbian Museum, the Academy of Sciences, the Historical Society, the Art Institute, the John Crerar, the Newberry, and the Chicago Public Libraries and the University. The Field Columbian Museum, which was opened in August 1893, during the Chicago International Exhibition, under the title of the Columbian Museum of Chicago, owes its existence to private liberality, and in May 1894 was renamed in honour of its founder, Mr. M. Field, of the firm of Marshall Field and Co. On Saturdays and Sundays the Museum is open free to the public, but on other days a small admission fee is charged, although the scholars attending elementary and secondary schools are always admitted without charge. Dr. Meyer furnishes his readers with a plan of the ground floor and another of the galleries, and discusses the general arrangement of the rich collections and the mode of cataloguing. At the conclusion of his article he expresses himself dissatisfied with the building, which he considers inadequate to the contents, urging that if this were remodelled the Museum ought to take rank among the first in the world.

Of the other institutions named, Dr. Meyer considers that the small museum of the Academy of Sciences is a model of its kind; and that the Art Museum is in many respects remarkable, and, like the other institutions, worthy the best attention of all interested in such matters. The Newberry and John Crerar Libraries, which are for reference only, display many features of their own, and will in the near future be of the highest importance as the scientific libraries of the Central United States. The Chicago Public Library, on the other hand, is a circulating one, which lends out, according to the author, millions more volumes than any other institution in the world; it is, in fact, a unique institution. As to the University, which is described in considerable detail, Dr. Meyer has no doubt that it is assured of a great future, the progress it has made and the influence it exerts, after an existence of only a decade, being little less than marvellous.

To all practically interested in museum and library work and progress, Dr. Meyer's observations and criticisms should be invaluable. R. L.

The Mechanical Triumphs of the Ancient Egyptians. By Commander F. M. Barber, U.S. Navy. Pp. x + 123. (London: Kegan Paul and Co., Ltd., 1900.) Price 3s. 6d.

THE writer is a well-read sailor, who has devoted much time to answering as plausibly as possible the common query of travellers, "How did the Egyptians transport such great stones from their quarries as the stones for the pyramids, the colossi and obelisks, and lift them to their present positions?"

He discusses the Egyptian knowledge of the mechanical powers, the capstan and windlass known in the first three dynasties, the single pulley B C. 3500, the inclined plane very early, the screw and the Spanish windlass also early.

He thinks that the heavy stones of the lower parts of the pyramids were brought on rafts by water, then up long inclined planes of gentle slope to their actual positions. The lighter stones of the upper parts may have been lifted, possibly also the casing stones, by levers, but he finds reason to believe that the screw-jack was in common use for this and other purposes. He describes the quarrying, the carrying and polishing of very hard stones with such tools as the Egyptians possessed; he is much at home in his discussion of the shapes and strength of boats used for conveying two obelisks at a time and how they were towed, and he compares the modern methods of lifting obelisks into position with his plausible account of how the ancients performed such operations.

Cours de Mathématiques à l'Usage des Élèves-Architectes et Ingénieurs Professé à l'École des Beaux-Arts. Par Carlo Bourlet. Pp. iii+244. (Paris: C. Naud, 1902.) Price fr. 8.

THIS is an elementary treatise on what is often called higher mathematics, the parts of which are taken up in the following order:—Differential calculus; analytical geometry of two dimensions with calculus applications; integral calculus; three-dimensional geometry. It seems to be made up of the most elementary parts of three or four treatises, but there is nothing new in the treatment. One might have expected the author to illustrate the well-known rules of differentiation by showing how applicable they are to the problems of the builder and engineer, to have greatly shortened the proofs and lessened the number of rules for differentiation, and so forth; but we here find practically nothing of the kind. The conic sections are still the important curves; the student gets rules enough for the most elaborate differentiation and integration and, in fact, enters in the most orthodox way upon a course of pure mathematics; but this book is in no way written to satisfy the special needs of the architect or engineer. But the author is to be praised for teaching the calculus, in however dry a manner, before coordinate geometry. We wish he had used the calculus to help in teaching coordinate geometry, but he only makes a combination after he has taught both subjects.

Physical Determinations. By W. R. Kelsey, B.Sc., A.I.E.E. Pp. xii + 316. (London: Edward Arnold, no date.) Price 4s. 6d.

THIS book contains, in a space of 310 pages, 185 sections each of which deals with generally one and sometimes more experiments. The subject-matter spreads over the whole range of physics. It is consequently packed tightly; and so the author has had to omit details, but he has endeavoured to give sufficient information to enable a class to start work without waiting for individual instruction from the demonstrator. It is claimed that the book contains most of the exercises which have been set at the London Intermediate and B.Sc. examinations.

The exercises are of very variable degree of difficulty and are not graded, so that a teacher adopting this book for elementary classes will have to make a careful selection. One use of the book will be to look up the whole subject the night before an examination.

Proceedings of the Aristotelian Society. New Series. Vol. i. Pp. 239. (London: Williams and Norgate, 1901.)

THE existence of the Aristotelian Society illustrates one of the best features of English philosophical study, its freedom from the tendency, often so strongly marked in continental countries, to organise itself into little schools, each with some master, whose decisions are unquestionable, and his band of unquestioning disciples. The present volume, like its predecessors, is pleasingly marked by the tone of free inquiry and unprejudiced discussion natural to a society in which adherents of the most various philosophical principles attempt to make themselves reciprocally intelligible. The contents of the book include contributions to most departments of philosophy, except that there is no paper dealing directly with ethics. Among the essays concerned with metaphysics the most important are the three in which Dr. Shadworth Hodgson, the Nestor of the society, defends his well-known views on causation, substance, and the nature of the conscious subject of psychology, and the discussion of identity by Mr. G. E. Moore. Of the papers on other subjects perhaps the most attractive is Mr. Sturt's on "Art and Personality." Mr. Beneke's discussion of the "Aspect Theory of the Relation of Mind to Body" is suggestive, though impaired by the writer's voluntary abstention from metaphysical thoroughness. A. E. T.

The Play of Man. By Karl Groos. Translated by Elizabeth L. Baldwin. Pp. ix + 412. (London: Heinemann, 1901.)

PROF. GROOS'S work, "Der Spiel des Menschen," has already been noticed in this column, in connection with the appearance of the German original. It is therefore superfluous to say more than that the work, both for wealth of information, soundness of judgment and charm of literary style, is in every way worthy of its earlier companion study of "The Play of Animals." Apart from its purely psychological interest, the book has a serious value for the pedagogue who desires to form his own judgment as to the educational effects of games and the uses and dangers of the play-impulse. It is to be hoped that so good a book will have in its English dress the deserved success already attained in this country and America by "The Play of Animals." The translator has done her work well, and Prof. Baldwin contributes a preface and a few footnotes.

LETTERS TO THE EDITOR.

The Red (C) Line of Hydrogen and the Zeeman Effect.

FOR some months we have been engaged in an investigation of the effect of a magnetic field on the more conspicuous lines of certain elementary gases, including the case of helium referred to by Prof. Gray and Dr. Stewart in your issue of November 21. We have employed a very fine echelon grating of twenty-six plates by Hilger. One observation that we have already made is, perhaps, of sufficient interest to deserve mention in your columns. The red (C) line of hydrogen was unmistakably divided before the application of the magnetic field. A reference to Michelson's papers on the application of interference methods to spectroscopic measurements showed that he had announced the red hydrogen line to be a very close double as long ago as 1887. A more detailed examination of the visibility curve is given in the *Philosophical Magazine* for September, 1892, from which it appears that the curve is practically the same as that due to a double source, whose components have the intensity ratio 7 : 10, and in each of which the light is distributed according to the exponential law resulting from Maxwell's theory of velocities. The distance between the components is given as $1\cdot4\times10^{-3}$ millim., so that it should be well within the power of the echelon as at present constructed to resolve the line.

Under the influence of the magnetic field each component is widened, and by using a double-image prism as recommended by the late Prof. Preston to separate the constituents, is seen to give rise to the normal triplet.

It is necessary for these observations to use a vacuum tube giving a bright crimson light in the capillary portion, and it is an advantage to have the tube in connection with the pump and a supply of hydrogen while under observation.

We hope to be able to publish quantitative results regarding this and other lines when our researches are further advanced.

BLYTHSWOOD,
H. S. ALLEN.

Blythswood Laboratory, Renfrew, N.B., November 25.

On the Probability that the Son of a very highly-gifted Father will be no less Gifted.

AN abstract was presented last Thursday to the Royal Society by Prof. Karl Pearson of results that apparently showed in a most conclusive way "that the mental characters in man are inherited in precisely the same manner as the physical." His data and work have yet to be communicated, but the figures, which were given separately, for four physical characters in from 800 to 1000 pairs of brothers, and for seven mental characters in another equally large set, are closely the same in all eleven instances, and they seem to substantiate his conclusion up to the hilt.

As the question of inherited ability may thus be brought again to the front, perhaps you will allow me space to refute a specious objection which is likely to be adduced, as it has already been urged with wearisome iteration, namely, that the sons of those intellectual giants whom history records, have rarely equalled or surpassed their fathers. In reply, I will confine myself to a single consideration and, ignoring what Lombroso and his school might urge in explanation, will now show what would be expected if these great men were as fertile and as healthy as the rest of mankind.

The objectors fail to appreciate the magnitude of the drop in the scale of intelligence, from the position occupied by the highly exceptional father down to the level of his *genetic* focus (as I have called it), that is to the point from which his offspring deviate, some upwards, some downwards. They do not seem to understand that only those sons whose upward deviation exceeds the downward drop can attain to or surpass the paternal level of intelligence, and how rare those wide deviations must be.

The exceptional quality of the father is only one of four elements that contribute in apparently equal shares to determine the position of the genetic focus. The other three are (1) the quality of the mother, (2) that of the paternal ancestry, (3) that of the maternal ancestry. In the case we are supposing the mother may occupy a high, though almost necessarily a lower, position on the scale of intelligence than the father. Where, for instance, could an intellectual giant like Napoleon find an equal mate? The average ancestry, whether of the father or of the mother, are always more or less mediocre, some ancestors being above and others below the general level of intelligence. Consequently the exceptional quality of the father, considered apart from his ancestry, is not likely to raise the position of the joint genetic focus of himself and the mother by more than a quarter of its amount. Let us consider the far from overstrained case of a father whose intelligence exceeds mediocrity by an amount that lies between seven and eight times that of the "probable error" of the distribution of racial intelligence. Extending the nomenclature employed in my lecture, which you published on October 31, his class would be Y. I will suppose his wife to be a woman of such ability that her equal is only to be found once in every fifty persons, that is of class U. Then the class of the mid-parent would be half-way between Y and U, or W. Regression which is due to the joint ancestral influences would degrade W by at least two classes, that is from W to U, which makes a total drop of four classes from the Y from which we started. Only those children who deviate upwards to that large extent can equal their father. But the conditions are still harder than they appear, because of the closeness with which the sons are clustered round the common filial (or genetic) centre. Their modulus of deviation is less than that of racial deviation, so that it would need fully five steps of filial deviation to reach the required level, and hardly one in 300 deviates do that. He might have many sons more or less distinguished, sons classifiable as W, X, or V, as experience shows to be the case, but the probability of a Y father having a Y son is remote. All the same, a Y father is more likely than any one man of a lower class than his own to have such offspring, but as the latter are very numerous the supply of Y men comes chiefly from them.

I have looked again at my "Hereditary Genius," written many years ago, under the light of newer knowledge, and feel that the evidence there recorded of the inheritance of ability is quite as strong as theory would lead us to expect.

I must not trespass further on your space, though the subject tempts one to go far into details. FRANCIS GALTON.

Pigments of Nudibranchiate Mollusca.

LAST summer, on the coast of California, I had occasion to study three species of the beautiful genus Chromodoris, all of them hitherto undescribed. Technical descriptions have been sent for publication elsewhere, but the purpose of the present note is to call attention to the interesting pigments possessed by these animals. *C. universitatis* (so called because it bears the colours of the University of California) is a large species, more than 2½ inches in length, of a rich dark ultramarine blue, the edges of the mantle and foot bright cobalt blue. The mantle has two longitudinal series of oblong very bright orange spots, about seven in a series; there are also five orange spots on the anterior part of the mantle. The sides of the foot also exhibit a row of orange spots.

When the animal is placed in formalin (4 per cent.) it immediately gives into solution a strong blue colour. This colour is even dissolved out, though more slowly, by sea water after the death of the animal. The blue solution is bleached by caustic potash, and is immediately turned pink (about the colour of apricot flowers) by hydrochloric acid.

The orange spots are not affected by formalin, but, curiously, when seen through the blue solution, they appear bright red. *C. porterae* (from La Jolla) is a small species, about 11 mm. long, blue as in the first species, with two rather broad longitudinal stripes of bright orange on the mantle. There is an inconspicuous median line of a lighter blue. After death the blue (evidently the same pigment as that of *C. universitatis*) dissolves out, and the body becomes a sort of pale greenish, with the dorsal stripe on the mantle very white. The orange bands are not affected.

The third species, *C. mcfarlandi* (from La Jolla and San Pedro), is about 35 mm. long, the mantle brilliant purple with a yellow margin and three longitudinal yellow stripes. The end

of the foot is purple, with a longitudinal orange stripe. The orange pigment is evidently the same as that of the other species, but the purple is different from the blue and does not dissolve out in formalin.

No doubt all these pigments represent "warning coloration."

East Las Vegas, N.M., U.S.A., November 10.

The Ash Constituents of Some Lakeland Leaves.

A FURTHER series of experiments bearing on the question indicated in this journal (vol. lxiii., No. 1634, p. 396) was undertaken during the summer and autumn of this year. It was deemed advisable to extend the research over a pretty wide range of subjects, so as to be able, if possible, to catch some kind of clue towards the correct elucidation of the causes operative in the case. The capital object in view was to ascertain the exact amount of inorganic constituents (especially silica and lime) which the leaves extract from the soil at different periods of their life, so as to determine whether this particular amount has any connection with the chemical composition, &c., of that particular soil. In all cases the entire leaf and petiole were used dried at 100° and then incinerated, the same vessel and the same source of heat being used for each separate incineration.

Leaves of	Date.	Percentage of crude ash.	Percentage of silica (SiO_2) and of lime (CaO) in the crude ash.	
			SiO_2	CaO
Beech	May 17	4·8		
,, ...	July 30	5	17	27·4
,, (brown)	Nov. 3	6·8	27·2	23·7
Oak	Aug. 17	5·8	12·2	29
,, (brown)	Nov. 3	6·8	14·5	37·5
Hazel	June 10	3·3		
,, ...	Aug. 4	5·7	6·2	26·8
,, (orange)	Oct. 27	6·3	15	28·6
Alder	July 29	4·9	1·8	31
,, (falling)	Nov. 1	5·7	1·7	33·6
Linden	May 30	5·5		
,, (yellow and brown)	Oct. 18	10·8	2·5	34·8
Ash	June 12	7·7		
,, ...	Aug. 2	6·7	1·5	37·7
,, (yellow)	Oct. 27	9·5	5·3	34·3
Elder	May 21	8·7		
,, (yellow)	Oct. 24	8·5	9·5	31·5
Scots pine (old leaves)	Aug. 19	2·5	9·4	15·9

On reviewing the foregoing table there would seem at first sight to be nothing remarkable therein; but a little collation and comparison serve to throw a more searching light upon the subject. All these trees and shrubs have sprung from a siliceous gravelly soil charged with basic constituents, but rather poor in lime (well under 12 per cent.). Nevertheless, the leaves of ash, alder and oak have managed to secure an amount of lime which may be regarded as nearly, if not quite, their full complement of that substance. The high proportion of lime in alder leaves may be referred to the very low proportion of silica; but this is hardly feasible in the case of the ash and oak. The ash-leaf, with a feeble proportion of silica, maintains a considerable quantity of potass and an amount of lime necessary to neutralise the organic acids which it produces in very notable degree. The oak-leaf, with far less potass in autumn, demands for the annulment of its organic acids (chiefly oxalic) a supply of lime apparently commensurate with its unique faculty for the production of starch. It will be specially observed that while, as indicated by the similar ratio of ash, the leaves of beech and oak have reached on November 3 a coequal measure of decay, that of the beech is evidently farther fallen. The leaves were selected for the experiment from beech trees flourishing right vigorously on the sandy shelving banks of the bays which indent the upper reach of Ullswater. The result was so remarkable that the experiment was repeated with every care and precaution, but the amount of silica remained as imperturbably high as before. The tree is a decisive alien in Lakeland and its seeds never ripen here, but in a sheltered situation on a sandy bottom it presents an aspect of unquestionable health and sturdy adaptation to the circumstances.

P. Q. KEEGAN.

Patterdale, Westmorland.

Note on a Point of Chemical Nomenclature.

THE use made by Mr. Goodwin and myself, in a recent communication to the Chemical Society, of the term *alphyl* is the occasion of an interesting letter from "A. T. de M.," published in NATURE (October 31, p. 648). The history of the term *alphyl* and its replacement by Prof. Vorländer's term *arryl*, or, better, *aryl*, the form in which it has been generally adopted, is correctly stated. In the interest of so important a matter as uniformity in chemical nomenclature I willingly agree with "A. T. de M.," and will adopt *aryl* instead of *alphyl* for monovalent aromatic hydrocarbon radicals (C_6H_5, $C_6H_4CH_3$, &c.).

But Prof. Vorländer goes further than this, and his view is advocated by "A. T. de M." He proposes to alter the well-understood meaning of the term *alkyl*, to retain the term *alphyl* with a new meaning and to introduce the combination *alpharyl*. These proposals seem to me not only confusing, but unnecessary. Let us retain *alkyl* in its old meaning, adopt *aryl* for monovalent aromatic hydrocarbon radicals and use *acyl* for all monovalent acid radicals. The terms *alkylene*, *arylene* and *acylene* might be adopted for the corresponding divalent radicals without introducing a new termination. For the radical benzyl and its homologues, if it be thought desirable, *ar-alkyl* could be employed.

ALFRED SENIER.

Queen's College, Galway, November 17.

Does Man use his Arms in Locomotion?

IN "Monkeys; Their Affinities and Distribution," by Dr. A. R. Wallace (reprinted in his "Studies; Scientific and Social," vol. i.), the author gives (p. 183) as one of the characters in which man *differs* from all the monkey tribe—"*the perfect freedom of the hands from all part in locomotion.*"

My object in writing is to point out the peculiar way in which the majority of people move their arms and hands when walking or running. One may safely say that everybody, adults and children, at one time or another exercise this movement. The natural way in which children run is to "paddle" with the arms and hands, though trained runners do not do so.

Now is it not possible that this muscular movement of the fore-limbs in opposite directions in the act of locomotion is a survival of the four-legged mode of progression of man's remote ancestors? The anthropoid apes, we know, get about by the aid of their arms and hands; while the baboons walk much in the same way as dogs do. The examples and illustrations could be enlarged upon indefinitely, and it is not for me to do so. I believe that this theory has been thought of before, but I am unable to find any trace of it in the books I have consulted. I should be very grateful if any of your readers would enlighten me on the subject.

BASIL W. MARTIN.

Elm House, Hampstead.

CELEBRATION OF THE JUBILEE OF M. BERTHELOT.

THE Berthelot jubilee, celebrating the fiftieth anniversary of the publication of Marcellin Berthelot's first scientific work, was held in the Great Hall of the Sorbonne, in the University of Paris, on Sunday, November 24. The President of the Republic, M. Loubet, was in the chair, surrounded by the Ministers of the Cabinet, the Ambassadors of the various countries in the French capital, and numerous delegates from foreign and from local scientific societies.

The hall, a large amphitheatre, capable of seating more than 3000 persons, was packed with those who delighted to do honour to M. Berthelot. Behind the daïs, in the

front of which the President was seated, is a large fresco representing Arts and Science; and round the amphitheatre there are niches containing busts of Robert de Sorbon, the founder of the Sorbonne, or University of Paris; of Richelieu, Pascal, Descartes, Lavoisier and Rollin—the *élite* of the Frenchmen who have exercised influence on French education and on arts and sciences. On the right of the President the band of the Garde Républicaine welcomed him with the Marseillaise, the audience all standing, and the proceedings began punctually at 10 a.m. They were opened by a discourse from the Ministre de l'Instruction publique, M. Leygues, who gave an impassioned address on the services which M. Berthelot had rendered to French education; he noted how the ubiquity of M. Berthelot's genius had led him to pay attention, not merely to scientific work, but also to extend his purview to the systems pursued in schools and to the primary and secondary education of French citizens. M. Darboux, sécretaire perpetuel of the Academy of Sciences, in a careful and well-delivered address, alluded specially to M. Berthelot's contributions to general science and to the recognition of his labours, testified by the international response to requests for subscriptions, and to the numerous societies and associations which had presented him with addresses. M. Darboux was succeeded by M. Fouqué, president of the Academy of Sciences, who echoed what M. Darboux had said and expressed the gratification of the Academy that one of its members, who had devoted his life to the pursuit of truth for its own sake, had, in receiving respect and recognition from the whole civilised world, conferred honour on the body of which he had so long been a member, and whose proceedings he had enriched by so many valuable contributions.

M. Moissan, now professor of chemistry at the Sorbonne, gave in his address an account in general terms of M. Berthelot's contributions to chemical science. As early as 1855 Berthelot's work on sugar, which led to the synthesis of formic acid and of alcohol, directed the attention of chemists, who had formerly regarded analysis as the chief aim and end of chemical work, to synthesis. Although the idea of a "vital force" had been attacked by Wöhler and Liebig, still Berthelot, by numerous brilliant syntheses, contributed more than anyone, during the decade 1855–65, to render the idea untenable. In this he was helped by his friends Pasteur and Claude Bernard, each of whom, at the later date, was laying the foundations of the work which rendered his name immortal. M. Moissan aptly remarked, in alluding to "vital force," "nous avons d'autant plus de théories que la chose est moins claire." Sketching rapidly Berthelot's work on acetylene, on explosives, on thermochemistry, on the absorption of nitrogen by plants, and his contributions to chemical history, he having translated and edited numerous Greek and Arabic writers on the subject, he concluded by the remark that, owing to the universality of his knowledge and attainments, M. Berthelot must be regarded as the last of the "encyclopædists." The address was concluded by the phrase, "Nous vous remercions pour nous avoir donné un peu plus de la verité."

M. Gaston Paris, one of the executive of the Collège de France, was the next speaker. He alluded to the long connection which had subsisted between M. Berthelot and the Collège de France. In 1851 he was recommended by Balard as deserving of the position of his "préparateur," or assistant. After eight years, however, he migrated to the École de Pharmacie, where, in 1865, he was made "Professeur titulé" of organic chemistry. Shortly after, however, he was recalled to his old home, the Collège de France, where he has remained ever since, in spite of numerous calls to accept more lucrative positions elsewhere.

After a few words from the president of the Academy of Medicine, Emil Fischer, the eminent professor of chemistry of Berlin, read an address in German from the Prussian Academy of Sciences, and at the same time presented one from the German Chemical Society; Dr. J. H. Gladstone followed, introducing first Prof. Ramsay, who, after a few prefatory remarks, read the address sent by the Royal Society, and next Prof. Emerson Reynolds, who presented an address from the Chemical Society, of which he is president; and lastly Dr. Gladstone handed in an address from the Royal Institution. Prof. Lieben, of Vienna, conveyed the congratulations of the Imperial Academy of Vienna; and Prof. Guareschi, those from the Academy of Turin. M. Troost, the former professor at the Sorbonne, read a list of academies and societies which had sent congratulatory addresses, so numerous that nearly a quarter of an hour was occupied by the mere recitation of the names; and concluded by reading a personal telegram from the King of the Belgians, conveying His Majesty's felicitations, and announcing that the Queen Regent of Spain had conferred on M. Berthelot the Grand Cordon of the Order of Charles III.

The following translation of M. Berthelot's speech in acknowledgment of the tribute to his genius and scientific work is from Monday's *Times*:—

I am deeply touched and really embarrassed by the homage which you are offering me to-day. These honours, I am aware, are not due merely to your affection for my person, I must attribute them also to my age, my long labours, and to certain services which I have been able to render to our Fatherland and to my fellow men. Your sympathy makes the lamp which is about to be extinguished in the everlasting night shine with a final brilliancy. The respect of humanity for old men is the expression of the solidarity uniting present generations with those that have preceded us and with those that are to follow. What we are, in fact, is only to a very slight degree attributable to our personal labour and individuality. We owe it almost entirely to our ancestors, ancestors by blood and our spiritual ancestors. If each of us adds something to the common domain in the field of science, of art, of morality, it is because a long series of generations have lived, worked, thought and suffered before us. It is the patient labours of our predecessors who created the science that you are honouring to-day. Each of us, whatever his individual initiative, must also attribute a considerable portion of his success to contemporary *savants* concurring with him in the great common task. In fact, no one—let us proclaim it loudly—no one has the right to lay exclusive claim to any of the brilliant discoveries of the past century. Science is essentially a collective work, prosecuted during the course of time by the efforts of a multitude of workers of all ages and every nation succeeding one another and associated by a tacit understanding for the search of pure truth, and for the application of this truth to the continuous transformation of the condition of all men.

Of yore *savants* were looked upon as a little group of amateurs and men of leisure maintained at the charge of the working classes, and executing a task of luxury and pure curiosity for the amusement and distraction of those favoured by fortune. This narrow and unjust view which paid so little heed to our devotion to the truth and our services, this prejudice, finally disappeared when the development of science showed that the laws of nature were applicable to the practice of industries, and had as a consequence the substitution for the old traditional and empirical receipts of the profitable rules of the theories based on observation and experience. To-day who would venture to regard science as a sterile amusement in presence of the general increase of national and private wealth which results therefrom? To confine ourselves to mentioning the most interesting perhaps of the services which science has rendered, it suffices to compare the servile and miserable condition of the popular classes in the past as revealed to us by historical documents with their condition at present, already so advanced in dignity and well-being without counting the just hopes of which they are pursuing the realisation. Is there a statesman who doubts the services, greater still, which are to be looked for as the result of this incessant progress? Science

is the benefactor of mankind. Thus it is that the tangible utility of scientific results has convinced the State that laboratory work should be encouraged and sustained, because it is economically a benefit to all, and for the public health. Science carries still further its legitimate pretensions. It claims to-day at once the material direction, the intellectual direction, and the moral direction of human society. Under its impulse modern civilisation marches with a more and more rapid stride.

Since the first half of the century that has just gone by, not to go further back, the world has strangely changed its face. Men of my generation have beheld coming on the scene by the side of and above that nature which had been known since antiquity, if not an antiphysis, a counter nature, as is sometimes said, yet a superior and in a way transcendent nature where the power of the individual is multiplied a hundredfold by the transformation, hitherto unknown or not understood, borrowed from light, magnetism and electricity. Nor is this all. Let us rise to a loftier and more fruitful range of ideas. From the deeper knowledge of the universe and the physical and moral constitution of man there results a fresh conception of human destiny governed by the fundamental ideas of human solidarity between all classes and all nations. In proportion as the ties uniting the peoples are multiplied and made tighter by the progress of science and the unity of doctrines and precepts which science deduces from the facts which it notes and which it imposes without violence, yet relentlessly, upon all convictions, these ideas have assumed a growing and more and more irresistible importance. They are tending to become the purely human bases of moral life and of the politics of the future. Hence the *rôle* of *savants* as individuals and as a social class has constantly grown in modern States.

But our duties towards other men grow at the same time, let us never forget that. Let us proclaim it in this enclosure, in this palace of French science. It is for no selfish satisfaction of our private vanity that to-day the world does homage to the *savants*. No! It is because it is aware that a *savant* really worthy of the name devotes a disinterested life to the great work of our epoch, I mean to the amelioration, too slow, alas, to our mind, of the lot of all, from the rich and fortunate to the humble, the poor, the suffering. This was what nine years ago in this very hall the State and the authorities affirmed by honouring Pasteur. This is what my friend Chaplain has sought to express on this fine medal which the President of the Republic is to offer me. I know not if I have completely fulfilled the noble ideal traced by the artist, but I have striven, at all events, to make it the object and the end, the governing aim of my existence.

The medal (or rather *plaque*) with suitable inscription was then presented to M. Berthelot by M. Loubet, the President of the Republic, and, according to continental fashion, the ceremony was concluded with a fraternal embrace.

Such is a brief account of the proceedings at this very interesting ceremony; and one is led to seek for analogies in our own country. The Kelvin jubilee at Glasgow and the Stokes jubilee at Cambridge may be cited as events of a similar character; but in France the ceremony appeared to be of greater national importance, owing to the presence of the Head of the State, the Ministers and the Ambassadors. In his reply M. Berthelot alluded humorously to the former position of science; it was regarded as a harmless pursuit, carried on by amateurs and men of leisure at the charge of the working classes, for the amusement and distraction of those favoured by fortune; it has now become one of the most potent influences for civilisation that the world has known, and will ever retain that position. Is it possible that in England the former view of science still retains some hold on the people, and that in France this aspect of science has long been outlived? Whether this be so or not it is certain that all Englishmen will join with the whole French nation in congratulating M. Berthelot on the completion of so many years of work, and will wish him health and a long life during which he may enrich the world by further investigations into the wide domain of Nature.

BERTHELOT, AND THE METALS OF ANTIQUITY.

THE metals of antiquity are among the many subjects which, from time to time, have been studied by M. Berthelot. It is principally by two different methods that he has investigated the matter: (1) the writings of ancient alchymists, (2) the analysis of metallic objects sent him by modern explorers. In 1885 Berthelot published a handsome volume, "Les Origines de l'Alchimie," in which he described his researches among the Greek papyri, and the still older documents of the Egyptian, Chaldean, Jewish, Gnostic and Chinese philosophers. In succeeding years he brought out several volumes under the title of "Collection des Anciens Alchimistes Grecs," under the auspices of the Minister of Public Instruction.

By far the most important for the present purpose is the collection of papyri at Leyden. The Papyrus X is more especially chemical. It dates from the end of the third century, but contains the lore of earlier times. It is described in fairly full detail in the *Annales de Chimie et de Physique*, 1886, vol. ix. Berthelot shows that the earlier alchemy was not founded upon purely chimerical fancies, but rests upon positive experiment, by which the adepts made imitations of gold and silver and precious stones, or taught how to increase their weight. In interpreting these ancient writings we are met with a great difficulty in fixing the meaning of the terms used for the metals and gems and the preparations made from them, the vagueness of the language being augmented by the idea that these substances were susceptible of transmutation into one another, and also by the Platonic doctrine of a primary matter from which everything may be derived. In this particular papyrus there are no less than 101 receipts for making gold, asèm (electrum), silver, &c., and the processes to be adopted. These are described by Berthelot as being genuine and definite, and not overlaid with fanciful notions; but the later philosophers and commentators were strangers to practical work and governed by mystic ideas: thus there was supposed to be a connection between the seven known metals and the seven planets, seven colours and seven transmutations. The later alchymists threw their energies into the search after the philosopher's stone which was to transmute baser metals into gold.

More important, perhaps, than his studies of the ancient manuscripts has been the prominent part which Berthelot has taken in examining chemically the metallic objects which have been unearthed by the great explorers of the present day. These researches are being carried on over the greater part of the countries bordering the Mediterranean and extending to the Persian Gulf. It is hardly necessary to say that they are enabling us to picture to ourselves these great nationalities of old in a way that was never before possible. The part that Berthelot has taken is not that of an explorer, but that of a scientific analyst; and it has been mainly confined to the metals employed in these ancient civilisations. He commenced by examining different Assyrian objects from ancient Chaldæa, some from the palace of Sargon at Khorsabad, others from the mounds of Tello excavated by M. de Sarzec, now in the museum of the Louvre. M. Place had found in the palace of Sargon a stone coffer containing votive tablets, covered with cuneiform inscriptions giving the date of foundation of the palace as B.C. 706. Of the four now in the museum of the Louvre, one is of gold, another of silver, a third of bronze and the fourth of the rare mineral crystallised carbonate of magnesia. Judging from the inscriptions two of the other tablets are believed to have been of lead and tin. The discoveries at Tello consisted of a vase of antimony, a metal which had subsequently been lost sight of for many centuries; a tablet of metallic copper, much corroded, but free from tin; and a little figure of pure copper, bearing the name

of King Gudea, which fixes its date somewhere about 4000 years before the Christian era. This led Berthelot to speculate why these specimens were made of copper instead of the harder bronze, which, so far as his experience had then gone, was used by all the ancients. He applied to Maspero for some specimens of the oldest copper of which the date could be identified. Maspero recommended to him the so-called sceptre of Pepi I., an Egyptian king of the sixth dynasty, 3500–4000 B.C. This was in the British Museum, but, through the good offices of M. Waddington, it was placed in the hands of M. Berthelot with permission to analyse a small portion from the interior. It proved to be of pure copper. It was a natural supposition that tin was unknown in that remote age; and this was confirmed by the discovery in Chaldæa of some little figures serving to support votive tablets, associated with bricks that bore the name of King Ourmina, who is supposed to have reigned 4000 years B.C. They were also of copper, without either tin or zinc.

In the meantime Prof. Flinders Petrie had been carrying on his excavations in Egypt and had asked me to analyse some copper tools and utensils from early tombs and other ruins. They proved to contain little or no tin, though many of them contained arsenic. Evidence of the gradual transition from the use of pure copper to that of copper alloyed with tin was accumulating from various quarters, but the most striking, perhaps, was that furnished by Tell el Hesy, the Lachish of scripture. It was explored by Mr. F. J. Bliss, and is described in his book entitled "A Mound of Many Cities." The lower portion of this mound represents the Amorite city, dating about 1700 B.C.; it contained large weapons of war made of copper without admixture of tin. Above this are the remains of the Israelitish city, where the copper is replaced by bronze, till in the upper layers of the mound the bronze is gradually replaced by iron. Greece has also furnished its contributions. The analyses of Roberts-Austen, Damour and others had shown that the implements first used at Tyryns, Mikenai and other towns were of copper with little, if any, admixture of tin; and similar evidence is coming forward from Cyprus, Crete and other quarters. At Hissarlik, the reputed Troy, the analysis of the objects found in the first and second cities showed that they were made of copper with mere traces of tin, while in the third and more recent cities the copper was mixed with varying amounts of tin, from 4 to 8 per cent. or thereabouts.

These researches were followed by an important paper in the *Annales* of 1895, in which Berthelot discussed the nature and origin of the metals employed by the ancient Egyptians of various epochs, especially copper, tin, gold and silver. The general result was that up to the sixth dynasty the copper used was practically what they obtained from the ores; after this the copper was mixed with small quantities of tin, rarely exceeding 6 per cent. At about the twelfth dynasty 10 per cent. became the usual proportion, forming a very serviceable bronze, but occasionally as much as 16 per cent. was used.

In the same paper he investigates the cause of the "sickness" of copper objects in our museums. They often fall to pieces through the formation of atacamite, a cupric oxychloride. This is started by the presence of chloride of sodium in the soil and the carbonic acid and oxygen of the air, and is a curious and complicated case of continuous chemical action.

It became a matter of interest to explore the ancient workings for copper, turquoise and hæmatite in Wady Maghara in the Sinaitic peninsula, which is known to have been a source of supply in the time of the third Egyptian dynasty. M. de Morgan made a careful search, at M. Berthelot's instigation, and found not only specimens of the ores, but also remains of the tools that had been used. The mines are believed to have been abandoned about the time of the eighteenth dynasty, in consequence of the poverty of the ores. The tools were of copper, hardened sometimes by a little tin and at other times by arsenic.

More recently Berthelot has examined some copper objects found at Tello, believed to be of very high antiquity. One was a huge lance of very red metal, the others were adzes and hatchets. They were almost pure copper. It may be an open question whether any attempt was made at this period to harden copper by the introduction of other metals.

From the palace of Sargon there were also obtained objects of gold foil, which was not adulterated with copper or lead, but contained a considerable amount of silver; this, however, may simply indicate that as native gold commonly contains more or less silver, it had been used in the state in which it was found without any intentional admixture. Berthelot also tested some gold objects from Egypt, the one dating from the sixth and the other from the twelfth dynasty, and found the amount of silver varied from 3·2 to 4·5 per cent., while the gold of the Persian period was practically pure.

But a more ancient chapter of Egyptian archæology was opened by the recent researches of M. de Morgan, late Director-General of Antiquities in Egypt. He explored an enormous tomb of a very ancient king, which he supposes to be that of Menes, of the first dynasty, approximately 4400 B.C. Among the objects found here were a long bead and two or three other morsels of metal, which M. Berthelot certifies to be of gold, together with some articles in copper. Further explorations at or near Abydos, by M. Amélineau, have shown the existence of tombs of kings about the same period containing many copper utensils, which M. Berthelot found to be of almost pure metal, but sometimes containing a little arsenic.

These tombs are now being very carefully explored by Prof. Flinders Petrie, and the results are published by the "Egyptian Exploration Fund" in three large volumes, "Diospolis Parva," and "The Royal Tombs of the Earliest Dynasties," parts i. and ii. It would appear that in these prehistoric times the metals mostly used were gold and copper; objects made of silver and lead are found, but they are rare.

As gold occurs native and is of a striking colour, we need not wonder that it attracted the attention of men in the very earliest periods. It is astonishing the large amount of exquisite gold jewellery, inlaid with gems, that has been found, not only in the tombs of Queen Ahhotpu and of the four princesses buried at Dahshur about 2350 B.C., but in these far more ancient royal tombs. In one of them Flinders Petrie found four gold bracelets encircling the arm bone of a royal personage, presumably the wife of King Zer. These are made of gold, set with turquoises and amethysts, and so beautifully wrought that the soldering cannot be detected by the eye. My analysis of the gold foil found in three of these tombs showed that it contained about 13 per cent. of silver, and was evidently the pale gold commonly known in the Levant. The gold worked in the Nubian mines appears to have been of a purer quality.

The last paper that has been communicated by Berthelot contains a description of a very curious case, or shrine, found at Thebes. It is of the time of Queen Shapenapit, daughter of King Piankhi, who lived in the latter part of the seventh century B.C. This inlaid case is remarkable as containing, in addition to the ordinary metals of the time, a small piece of crude platinum, weighing between five and six milligrammes. It had evidently been worked with the hammer, and had probably been mistaken by the artificer for silver.

Though not himself one of the explorers in the field, Berthelot must ever be remembered for the important part he has taken in drawing attention to, and interpreting the results of their wonderful discoveries.

J. H. GLADSTONE.

THE USE OF THE WIRE SAW FOR QUARRYING.

PROF. C. LE NEVE FOSTER has conferred a great benefit on the Welsh mining industry by directing attention to a new method of slate-mining recently tried in the Pyrenees. At Labassère the wire saw is employed to make horizontal cuts across the inclined beds of slate, severing off great blocks without blasting. Believing that a similar system could be employed with advantage in North Wales, Prof. Le Neve Foster recommended that Mr. G. J. Williams, H.M. Assistant Inspector of Mines, should study the question on the spot. The Home Secretary having acceded to this suggestion, Mr. Williams has drawn up a very valuable report, which is published as an appendix to Prof. Le Neve Foster's annual report to the Home Office for the year 1900. The investigation clearly shows that slate might be worked in many quarries in North Wales by the wire saw method with conspicuous advantages. There would be lessened blasting, fewer falls of ground, less waste of good rock, reduced cost of working, less cost of explosives, a saving in the cost of unproductive work, a saving in the cost of removing rubbish, no need of quarrying worthless rock in underground workings, and the cost of examining and securing the roofs and pillars would be done away with.

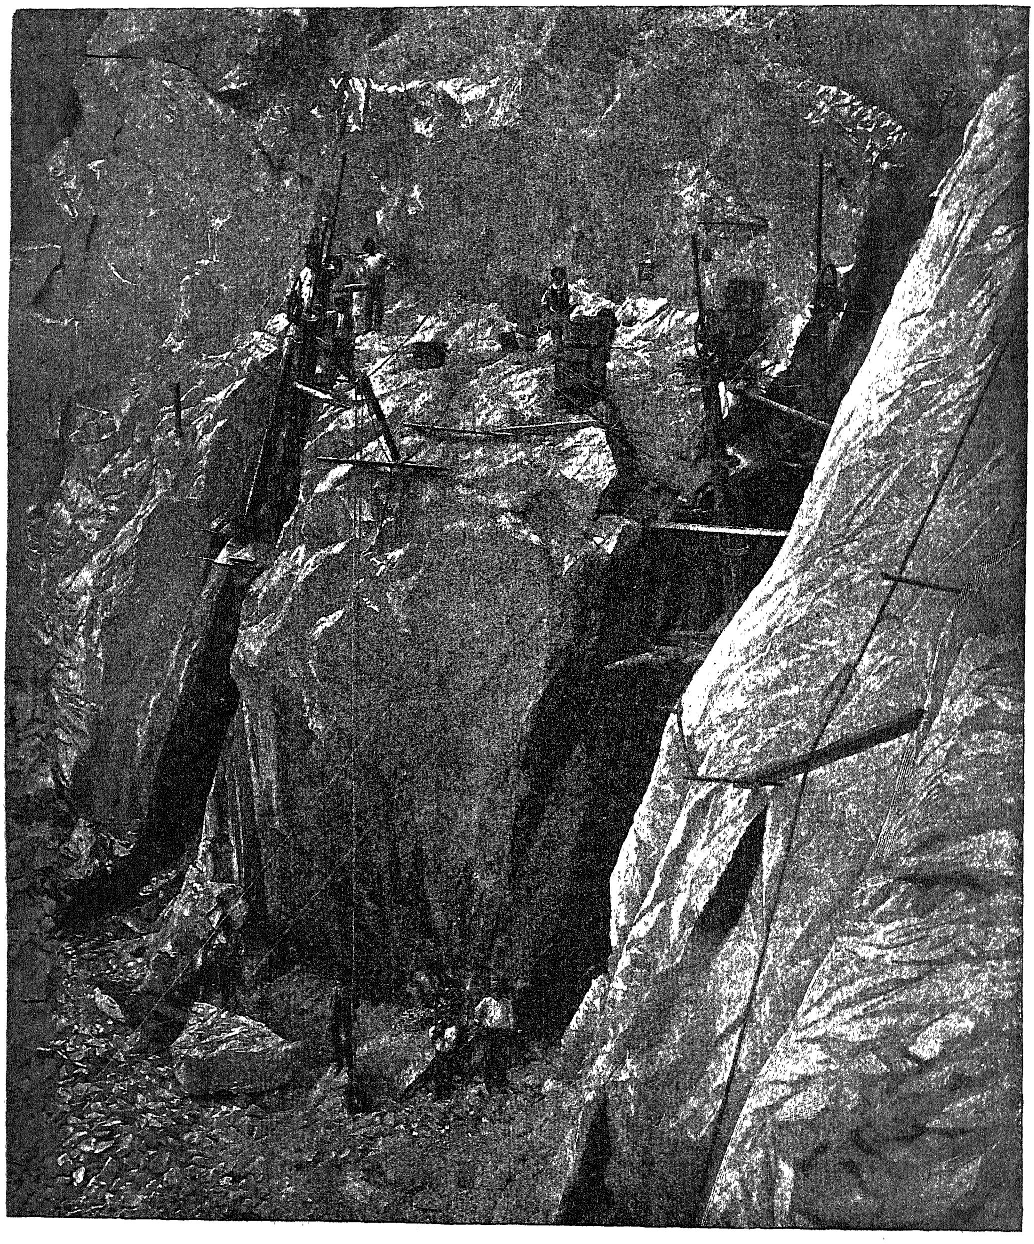

FIG. 1.—Use of the wire saw at Carrara.

The helicoidal wire saw has been employed for quarrying marble in Belgium and in Italy for some years. It is an endless cord, composed of three hard wires twisted together, which is made to travel along by machinery and

KNOWLEDGE

DIARY AND SCIENTIFIC HANDBOOK

For 1902.

(ISSUED IN CONJUNCTION WITH "KNOWLEDGE").

What the Press say:

THE DAILY TELEGRAPH.—"The result is highly satisfactory, and appears to respond very adequately to the request made for the publication of a volume of this nature."

NATURE.—"Will doubtless prove a great convenience. A variety of useful tables and articles of more than passing interest."

ENGLISH MECHANIC.—"Much interesting matter."

SCIENTIFIC AMERICAN.—"The Diary alone is worth the moderate price asked for the entire work."

GUARDIAN.—"For the followers of science, especially astronomers, it can be heartily recommended."

WESTERN MAIL.—"Will be of great service to natural observers and science students."

DUBLIN EXPRESS.—"Persons engaged in scientific work will greet with pleasure this filling of a long felt want."

NEWCASTLE CHRONICLE.—"Should find many users, the scientific man not having been catered for in the past."

ABERDEEN FREE PRESS.—"To enumerate these features is to show that the work is one of much value."

ELECTRICITY.—"An excellent idea well carried out. Will be found useful by scientific workers of all classes."

ORDER FORM.

Orders should be placed at once to secure Copies.

READY END OF NOVEMBER.

London:

KNOWLEDGE OFFICE, 326, HIGH HOLBORN, W.C.;

AND OF ALL BOOKSELLERS AND RAILWAY BOOKSTALLS.

RICHARD CLAY AND SONS, LIMITED, PRINTERS, LONDON AND BUNGAY.

is fed continuously with sand and water, the sharp particles of sand gradually cutting a groove. As the groove is deepened the cord must necessarily be kept applied to the rock. This is effected by guiding-pulleys mounted in pits sunk at the ends of the proposed cut. These pulleys must be at least 20 inches in diameter, and the pits somewhat larger. For sinking these pits there are employed in some Belgian quarries a rotative borer composed of a steel tube cutting an annular groove. The wire saw was applied at Carrara for subdividing blocks of marble, but the impracticability of using the revolving cylinder or hand labour for sinking inclined pits was an obstacle to its further use. The difficulty was, however, overcome by Mr. A. Monticolo, who invented an ingenious appliance which he termed a penetrating pulley, with which it is possible to replace the somewhat costly pit by a bore-hole 3 inches in diameter. The penetrating pulley consists of a disc 20 inches in diameter and $\frac{1}{4}$ inch thick, with a semicircular groove round its periphery deep enough to take half the thickness of the wire, the other half projecting. The disc is mounted on a pivot and is supported by a hollow steel shaft of slightly smaller diameter than the bore-hole. To the shaft is attached a series of tubes of equal diameter forming a column that may be lengthened at will, in the interior of which is a fine tube serving for the lubrication of the pivots. As the cut deepens the pulley is fed down automatically by means of an eccentric. For cutting a groove, two bore-holes, to receive the shafts carrying the axes of the pulleys, are first made by hand or by the diamond drill.

The pulley was first applied in March 1898 at the Campanile quarry, Carrara, where cuts have been made 50 feet long and 16 feet deep, inclined at an angle of five degrees from the horizontal. The highly satisfactory results obtained with the penetrating pulley serve to show that there is a great saving of expense by the substitution of bore-holes for pits, far less waste of valuable marble, and increased rapidity of quarrying and consequently increased output.

Almost simultaneously with the publication of Mr. Williams' report, the *Revue Générale des Sciences* published an exhaustive article by Mr. J. Boyer on the present condition of the French marble industry. This article is profusely illustrated and contains a large amount of information relating to the use of the wire saw. From this article the two illustrations accompanying this note have been borrowed.

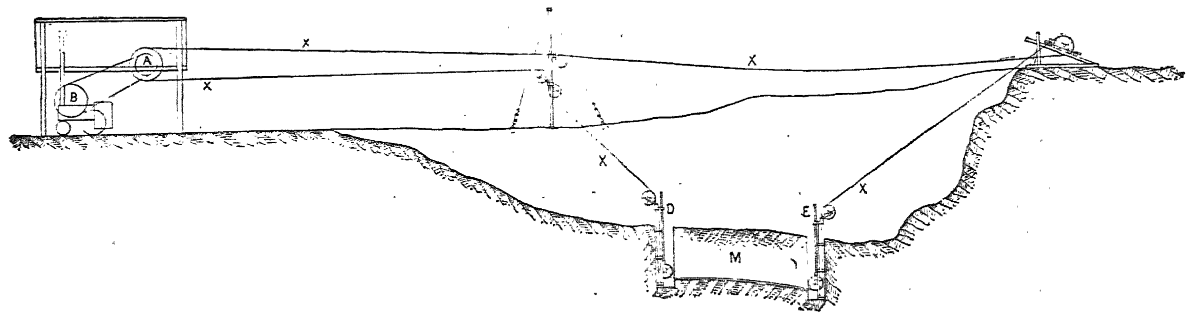

FIG. 2.—Installation of the helicoidal wire saw at a quarry. X, helicoidal wire; A, fixed pulley; B, motor; C, tightening arrangement; D, E, wire saw and grinding pulleys; M, block of marble being quarried.

NOTES.

DR. F. McCLEAN and Sir John Murray, whose names were included in the list of the new Council of the Royal Society given in NATURE of November 14, are unable to serve; and the two Fellows recommended for election in their places are the Right Hon. Sir John Gorst and Prof. H. H. Turner.

SIR WILLIAM ROBERTS-AUSTEN, K.C.B., F.R.S., will deliver the tenth "James Forrest" lecture at the Institution of Civil Engineers on April 17, 1902, the subject being "Metallurgy in Relation to Engineering."

THE governing committee of the Allegheny Observatory has decided to erect a 30-in. reflector at that institution as a memorial to the late Prof. Keeler. As it is expected that the funds subscribed will exceed the estimated cost of the instrument (2000*l.*), the balance will be used either to found a general fellowship for the study of astrophysics, or the award of a Keeler medal for work in the same field.

THE Royal Society of Public Medicine of Belgium has awarded Prof. Corfield, of University College, London, its bronze medal in recognition of his devotion to public health work.

A SUCCESSFUL kinematograph of the Severn bore was exhibited by Dr. Vaughan Cornish at the meeting of the Royal Geographical Society on Monday. This is, we believe, the first time that the impressive movement of a tidal bore has been recorded by photography and the phenomenon reproduced before an audience by a series of moving pictures.

A NEW Highland meteorological station has been established at Achariach in Glen Nevis, $4\frac{1}{2}$ miles S.E. of the Low Level Observatory at Fort William, and $2\frac{1}{4}$ miles S.W. of the observatory on Ben Nevis. The station is about 150 feet above sea-level, and the observations in the valley will be especially interesting in connection with the study of descending currents of cold air from the glens in the vicinity.

THE Council of the Royal Meteorological Society has designated Dr. Alexander Buchan, F.R.S., as the first recipient of the Symons gold medal in recognition of the valuable work which he has done in connection with meteorological science. This medal, which is to be awarded biennially, was founded in memory of the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and originator of the British Rainfall Organisation. The medal will be presented at the annual meeting of the Society on January 15, 1902.

A REUTER telegram announces that the *Gauss*, with the German Antarctic Expedition on board, arrived at Cape Town on Saturday morning, after being six weeks overdue. After leaving Hamburg on August 11 the *Gauss* touched at Las Palmas, and St. Vincent Islands. Deep-sea soundings were taken towards the west, but the ship did not go so far as the American coast. The *Gauss* was under sail the whole time, and the scientific observations made are said to be most satisfactory. The vessel will remain at Cape Town for ten days, and will then proceed to Kerguelen Island.

ON Monday evening M. Santos Dumont was entertained at dinner by the Aëro Club of the United Kingdom. The chair was taken by Major-General Lord Dundonald, and among the company present were the Brazilian Minister, Lord Suffield, Sir Norman Lockyer, Colonel Templer, director of military ballooning, Sir J. Crichton Browne, Prof. D. S. Capper, Colonel R. E. B. Crompton, R.E., Sir V. Kennett-Barrington, Prof. John Perry, Dr. Boverton Redwood, the Hon. C. S. Rolls and Mr. R. W. Wallace. In acknowledging the toast of his health, M. Santos Dumont said that he hoped in a few months' time to make some trials with a dirigible air-ship above London.

AN illustration of the way in which a disease present in one species or race in a mild form may produce most severe effects when introduced into a region inhabited by another race, has been sent to us by Prof. T. D. A. Cockerell. It appears from trustworthy reports that the natives of western Alaska are rapidly disappearing from the effects of an epidemic of measles. Dr. Moore, assistant surgeon of the United States quarantine service, states that at least one-third of the native population at Cape Prince of Wales, Nome, Port Clarence, St. Michael, Kuskokwim, Unalaska, Pribyloff Islands, Nunivak Island and St. Lawrence Island, and those along the Yukon River, have suffered from the effects of the epidemic, which at first was thought to be smallpox, but upon investigation proved to be measles. The epidemic originated at Holy Cross in north-eastern Siberia, and from that point it was carried to places visited by whalers, and the whalers carried the disease to Alaska. Dr. Moore reports the condition of the natives as being most pitiable.

A PAPER on "Fairies, Apparitions, Visions and Hallucinations" was read by Sir Lauder Brunton at a meeting of the Medico-Psychological Association last week. At the outset, attention was directed to the fact that there is considerable variation in the acuteness of the senses of different people. Thus some persons perceive blue flames in the fire in winter and some persons hear the shrieks of bats, whilst others are sensible of neither. In the same way there are people who feel things which others do not feel. Apparitions are probably due to abnormal conditions of the apparatus required for the reception of external impressions. The vessels inside the brain may be capable of contraction, like those outside, and in that case there would be anæmia of parts of the brain and consequently affections of vision, hearing, smell and taste. Epilepsy is connected in the minds of psychologists with migraine. In many people migraine is preceded by a vision of zigzags, rather like a procession. A troop of spirits in this form appears in Doré's illustrations to the "Inferno." It was suggested as not unlikely that both Dante and Doré suffered from headache of this kind. Stories of fairies might partly be referred to visions as well as to the aboriginal race mentioned by Prof. Rhys. Speaking of Mahomed, Sir Lauder Brunton described his visions, trembling fits and convulsions, and said it was curious to speculate how different might have been the course of the world's history if the prophet had been thoroughly dosed with bromide of potassium.

SIR WILLIAM PREECE, K.C.B., F.R.S., covered a wide field in the address which he delivered on November 20 at the opening of the new session of the Society of Arts. He surveyed the most prominent points of scientific progress during the nineteenth century, and from the trend of advancement suggested some developments of the immediate future. The great scientific discoveries of the past century dealt with in the address were (1) the principle of evolution; (2) the atomic structure of matter; (3) the existence of the æther and the undulatory theory of light; (4) the principles of electromagnetic induction and electrolysis; (5) the principle of the conservation of energy. Limitations of space prevent us from printing the address in full, but the following are a few extracts from it. The trend of research at the commencement of the twentieth century is to prove that the basis of all matter is fundamentally the same, and that the true atom has not yet been reached.—The criterion of true advance in knowledge is the possession of standards and of means of accurate measurement. We commence the twentieth century remarkably well equipped with both these requisites. The engineer has only to take care of his "Joules," or units of energy, and his machines will take care of themselves.—The only excuse for disaster due to magnetic disturbance is ignorance. The stars are always with us for guidance and comparison. Magnetic science must be maintained by well-equipped laboratories, by continuous observations, by the distribution of reports and by up-to-date records and corrections of charts. We seem to have learnt all we can of magnetism, and we commence the twentieth century without any indication of a new directing force. We have local magnetic disturbing elements to measure, and certain dangers due to storms, snow, rain and fog to remove. We want better warning of approach to land, and better communication between ship and ship and ship and shore. The twentieth century is bound to see great developments in this direction. In conclusion, Sir William Preece remarked:—"I hope that I have succeeded in showing that progress in all branches of life is due to certain motive causes working on the principle of evolution; that these causes are within the reach of our observation; and that they have only to be discovered, so that, by their encouragement, we may secure, during the coming century, greater and further advances in civilisation and knowledge."

MR. LANGDON, in his presidential address to the Institution of Electrical Engineers on Thursday last, dealt with the applications of electricity in railway engineering. Although in so doing he passed to a large extent over the same ground as he covered in his paper on the supersession of the steam by the electric locomotive in November 1900, he treated the subject from a more general and less technical standpoint. Hitherto electricity has played a small, but indispensable, part in the working of steam railways, for telephone, telegraph and lighting purposes; but Mr. Langdon realises that the problem of the conversion of our steam railroads is one pressing for immediate attention. The magnitude of the railway interests is so enormous that it is necessary to give the question the most careful consideration, or disastrous results may accrue. The reckless investment of capital in electric railways to compete with existing lines is not likely, Mr. Langdon points out, to be profitable for shareholders in either concern, and he seems to deprecate competition of the kind foreshadowed by the projected new electric railway between Manchester and Liverpool. It is, however, for the railway companies themselves to show that they are on the alert and are prepared to meet the growing demands of the country; for if the necessary reform does not come speedily from within, it is they, we think, who will be likely to suffer disaster. Electrical engineers have before them a work compared with which their past achievements are but trifling; in carrying it out let them by all means go carefully, but do not let them consider that synonymous with going slowly.

AMONG the notes in *The Engineer* (November 22) a remarkable motor-car performance is recorded. M. Fournier, the well-known French motorist, drove a 40-horse-power petrol car one mile in 51⅘ seconds, approximately 70 miles per hour. The tract was a straight and level piece of road known as the Ocean Parkway, New York.

A PAPER of much interest on the balancing of locomotives has just been read before the Institution of Mechanical Engineers

by Prof. W. E. Dalby. As is well known, although there are some engines with their reciprocating and revolving parts *unbalanced,* the counterpoising of the various parts forms a most important item in the designing of the engine, and a point which, if neglected, is afterwards easily discernible on the footplate. The paper, which is divided into nineteen separate articles, deals with the subject in a very lucid manner, and each article is thoroughly treated. We find taken as examples two typical English engines (a passenger and goods on the L. and Y. Railway) and an 8-coupled engine, class E Baldwin Company of America. In the article in which the distribution of the reciprocating mass between the coupled wheels is discussed, three figures are of special interest, being diagrams showing: (1) All revolving mass and two-thirds reciprocating mass in driving-wheel (only); (2) all revolving mass and two-thirds reciprocating mass equally distributed (on all wheels); (3) all revolving mass and all reciprocating mass equally distributed (on all wheels). In dealing with four-cylinder locomotives the author points out how balancing can be effected without the use of balance weights attached to the wheels, by properly proportioning the "masses" and "crank angles."

Symons's Meteorological Magazine for November contains a summary of the climate of the British Empire for the year 1900, so far as it can be represented by reports from eighteen stations distributed over various parts of the world. The highest temperature in the shade (112°·2) occurred at Adelaide on January 1; this station also registered the highest solar temperature, 170°·5. The maximum temperatures at London (95°·2 on July 16) and Toronto (98°·0 on August 6) are the highest noted for these stations since the commencement of the summary in 1877. The lowest shade temperature (−34°·8 on February 9) was recorded at Winnipeg, where the range in the course of the year was 135°·3. The driest stations were Adelaide and Fredericton (New Brunswick), where the mean humidity was 66 per cent., and the dampest station was Colombo, Ceylon, mean humidity 81 per cent. The greatest rainfall was at Calcutta, 89·3 inches, and the least at Malta, 16·1 inches.

THE pilot chart of the North Atlantic and Mediterranean for the month of December, just issued by the Meteorological Office, shows that there were still a few icebergs on the edge of the bank eastward of Newfoundland as late as October. On the great circle track to Belle Isle, and also within the Strait, there has been a perceptible diminution in the quantity of ice reported, so that from the scores of bergs sighted about July and August they have now dwindled to an occasional one. It is, however, interesting to notice in this connection that the Dundee whalers recently returned from Davis Strait report much ice blocking up the west side of the strait and drifting southward last summer, while in the early part of October what was probably a portion of the same ice was reported to be sweeping down along the Labrador coast in great quantities. There is thus some probability of the next ice season off the Newfoundland coast being an early one. Realising the importance to the mariner of a clear understanding of the laws governing the movements of cyclonic disturbances—how he should combine his observations of the wind direction with the barometric variations to obtain, under all circumstances, a fair idea of his position in the storm field, and to ascertain approximately the line of progression of the central part of the system—the article on Atlantic storm systems published in one of the earlier charts is reproduced at the commencement of the season of winter storms. An inset chart illustrates the conditions obtaining over north-western Europe during the north-westerly type of weather, that of December 1895 being in the ascendent for more than a fortnight. At this season the winds of the Mediterranean region are shown to be influenced by disturbances which follow two well-defined paths, one from the Bay of Biscay to Sardinia and away to Cyprus, the other taking a north-easterly course from about Gibraltar to Corsica and across Italy to Dalmatia.

MR. HALCOTT C. MORENO has published in the *Proceedings* of the American Academy of Arts and Sciences a paper on ruled loci in n-fold space. Corresponding to a developable and its edge of regression in ordinary space, we have the loci derived from a flat of $n-1$ dimensions whose equation involves a single arbitrary parameter, these loci representing the ultimate intersections of two, three or more flats of the family. In like manner loci corresponding to ruled surfaces are obtained from an $n-2$ flat whose equations involve a single parameter, and the further case is considered of an $n-k$ flat also involving a single parameter. Several of the conclusions obtained are analogues of results given for three-dimensional geometry in Salmon's well-known treatise.

THE accident to the aëroplane machine with which Herr Kress has been experimenting on the reservoir of the Vienna waterworks forms the subject of a critical article in the number, for November 16, of *Die Umschau*, a paper which has previously given several well-written articles on this and other systems of experimenting in aërial navigation. Herr Kress made the mistake of building the machine without waiting for the motor, and when the latter was at length obtained it was found to be a heavier one than he had ordered. This had the effect of making the apparatus top-heavy when sailing on the water on the aluminium boat which formed its car, and the accident occurred, not when the machine was going at full speed, but after the pace had been moderated and the apparatus was turning towards the bank. A small gust of wind catching the sails appears to have caused the machine to heel over to such an extent that it was incapable of righting itself. It is pointed out that stability in the water and stability in the air are quite different things, and Kress thinks that the high position of the centre of gravity would not have affected the stability of the machine if it had been supported in the air by its wings, nor would a side wind have had the same power of overturning it.

IN a recent issue of the *Proceedings* of the American Academy of Arts and Sciences (vol. iii. p. 507) Mr. E. C. Starks gives a complete list of the numerous synonyms which have been applied to the component bones of the fish-skeleton. It may be hoped that naturalists will agree to adopt the names selected by the author as the best designations of the individual bones.

TO the November issue of the *Zoologist* Capt. G. E. H. Barrett-Hamilton communicates a further note on the origin of sexual dimorphism and of nuptial weapons and ornament. In the same journal Mr. F. Cohern narrates his experiences during a bird-collecting trip to the north of Iceland, with a list of the species obtained. He speaks of the extraordinary abundance and tameness of the birds, and believes that he has obtained a new form of pipit, although this opinion does not appear to be shared by his fellow ornithologists.

THE August issue of the *Boletim* of the Para Museum contains a paper by Dr. E. Goeldi on two Brazilian rodents, one of which (*Blarinomys breviceps*) was first described from its fossil remains, but is now known also by a single recent example. The same author gives an illustrated description of the gigantic catfish of the Amazons locally known as the piraïba. In assigning to this fish a new scientific name (*Piratinga pira-aiba*) the author states that in its young state it has long since been described by Lichtenstein as *P. filamentosa.* If this be so, the new title seems superfluous.

THE whole of part iv. of vol. xiii. of the *Journal* of the College of Science of Tokio is occupied by an elaborate dissertation on the development, structure and metamorphosis of

that remarkable organism described in the larval form by Jahannes Müller in 1846 as Actinotrocha, and in the adult state by S. Wright in 1856 as Phoronis. The identification of the free-swimming Actinotrocha as the larva of the compound and stationary Phoronis is one of the discoveries for which science is indebted to Kowalewsky; but the question still remains undetermined whether the organism should be placed with the Gephyrean worms or with the Hemichordata. In spite of the numerous papers which have been devoted to this curious form, the author, Mr. Iwaji Ikeda, states that its life-history has hitherto been very imperfectly worked out, and it is to this that he has devoted much of his attention. Another point is the manner in which the free-swimming larvæ establish colonies in certain definite and limited localities. From the fact that the colonies are subject to periodical decay it is suggested that the organism annually changes its generation. It may be remarked that although in the title of the paper the name Actinotrocha is employed, in the text the family is alluded to as the Phoronidæ, while various species of Phoronis are mentioned.

NUMBER 12 of Sir George King's "Materials for a Flora of the Malayan Peninsula," reprinted from the *Journal* of the Asiatic Society of Bengal, is occupied entirely by the eleven genera of Myrtaceæ, including the ninety-six Malayan species of Eugenia.

WE have received the first three numbers of the *Bulletin* of the Imperial Botanic Garden of St. Petersburg, edited by Prof. A. Fischer v. Waldheim. The *Bulletin* is intended to appear at irregular intervals and to be devoted to original treatises, not before published, in all branches of botany, critical notices, and reports and communications from the Imperial Botanic Garden. In the present instalment the papers are in Russian, with brief French or German abstracts. They include articles on the Exoascaceæ of the Caucasus, "migrating lichens," biological observations on buckwheat, lichenological notes, &c.

THE origin and distribution of the cocoanut palm forms the subject of an interesting paper by Mr. O. F. Cook in a recent issue of the United States National Herbarium. It is contended that this most useful tree must have originated on the Pacific coast of South America and spread from thence to Polynesia and Asia. It is pointed out that all the other species of cocos are natives of South America. The cocoanut palm was found upon the Pacific coast by early Spanish explorers. Mr. Cook also claims an American origin for the banana and yam.

A RECENT number of the Australian *Town and Country Journal* is largely occupied with an illustrated account of the new mining school recently opened in connection with Sydney University. The erection of this school is largely due to the exertions of Prof. A. Liversidge, F.R.S. It is now well equipped with machinery and laboratories, and should prove of great value for training men to conduct metallurgical operations. The University of Sydney grants a degree in mining engineering, and the course of instruction given at the school is mainly in preparation for this degree.

LIEUT.-GENERAL C. A. MCMAHON contributes notes on some peridotites, serpentines, gabbros and associated rocks from Ladakh, north-western Himalaya, to the Memoirs of the Geological Survey of India (vol. xxxi. part iii.) These rocks are found intrusive in the Tertiary volcanic series. Mr. Vredenburg (vol. xxxii. part i.) discusses very fully the results of recent artesian experiments in India, pointing out that many of the so-called "artesian wells" are not fed by water under pressure. He gives records of numerous borings and concludes that artesian wells cannot be of utility in any extensive scheme of irrigation. Mr. T. H. Holland (vol. xxxiv. part i.) draws attention to a peculiar form of altered peridotite in the Mysore State, whereby a simple dunite has been changed into a breunnerite-picrolite-talc rock. He remarks that it is important to distinguish between this "primary" or contemporaneous alteration, due to the action of vapours originally contained in the magma, and the "secondary" changes that may be induced subsequently and are unconnected with the processes of consolidation.

THE publication of a ninth edition of "Stieler's Hand-Atlas" has been commenced by Mr. Justus Perthes, Gotha. The work will be issued in fifty parts, which will appear at intervals of two or three weeks.

PROF. ANDREW GRAY'S work on "Dynamics and Properties of Matter," being Part i. of his "Treatise on Physics" (J. and A. Churchill), is shortly to appear in the German language. The work of translating has been undertaken by Prof. Auerbach, of Jena.

A CATALOGUE of the Indian Decapod Crustacea in the collection of the Indian Museum, Calcutta, is in course of preparation by Major A. Alcock, F.R.S. It is proposed to issue the catalogue in three collateral and independent series, one for the Bachyura, another for the Macrura, and a third for the Anomura. The first fasciculus of Part i. has been received and contains an introduction to the monograph, and descriptions, with plates, of the Dromides or Dromiacea.

MR. JOHN HEYWOOD has published the second part of Book II. of "Machine Drawing for the use of Engineering Students in Science and Technical Schools and Colleges," by Mr. Thomas Jones and Mr. T. Gilbert Jones. The part contains forty-five plates, upon which drawings of engine and pump details are given; and descripitive text, with exercises, accompanies each plate. Students of engineering and machine construction will find the drawings of service in showing the details of engines and pumps constructed at the present time.

THE sixth part of Prof. A. Engler's elaborate monographs of the families and genera of African plants (Monographieen afrikanischer Pflanzen-Familien und -Gattungen) has been published by Mr. W. Engelmann, Leipzig, and can be obtained from Messrs. Williams and Norgate, London. The work, it will be remembered, is being prepared under the auspices of the Prussian Academy of Sciences, and when completed will be a most valuable account of the plants of the African continent. The present part deals with the Anonaceæ and is by Profs. Engler and L. Diels.

A SERIES of regional floras of India has been projected by the Director of the Botanical Survey of India, and the first part has been issued by Messrs. Taylor and Francis. In this volume Mr. T. Cooke deals with "The Flora of the Presidency of Bombay" from the order Ranunculaceæ to Rutaceæ. The increase of knowledge of the botany of the Presidency in recent years may be judged by the fact that the present part of the projected work (comprising 192 pages) contains descriptions of more than 130 species not included in Dalzell and Gibson's "Flora of Bombay," published in 1861. We propose to review the work when it has been completed.

MESSRS. G. PHILIP AND SON have recently published a pair of globes—one terrestrial and the other celestial—for the low price of three shillings. The globes are mounted on slender brass tripods, and each can be rotated on an axis. The diameter of each globe is four inches. It is, of course, not possible to represent any details upon a terrestrial globe of this size, or to find many stars by means of the celestial globe, but a young student may derive instruction from them as to the relative positions of the great land-masses of the earth and the meaning of the celestial sphere.

TEACHERS and students of botany often find it difficult to obtain the plants or other botanical material required by them for examination. A pamphlet received from Messrs. James Backhouse and Son, Ltd., The Nurseries, York, reminds us that this firm has a special scientific department for the purpose of supplying living and preserved material for use in classes or private study. Practically every specimen or preparation required in a course of botany is kept on hand ready for dispatch, and if it is not in stock it will be obtained. The facilities thus afforded for obtaining botanical material should promote the study of botany in schools and encourage investigation by private students.

SINCE the classical work of Bunsen on the cacodyl compounds, many attempts have been made to prepare monomethylarsine, the analogue of methylamine, hitherto without success. In the *Berichte* for November 9, Messrs. A. W. Palmer and W. H. Dehn give an account of the preparation of this substance in a pure state. Indications of the existence of such a compound were obtained three years ago, by the reduction of methyldichlorarsine, but as this is costly and difficult to prepare, a more suitable starting point was found in cacodylic acid. This on reduction with amalgamated zinc dust and hydrochloric acid gives the $CH_3.AsH_2$, which is separated from the hydrogen which accompanies it by passing through a U-tube surrounded by a mixture of solid carbon dioxide and ether. Monomethylarsine is a colourless, mobile liquid, which boils under ordinary atmospheric pressure at 2° C. and possesses the penetrating objectionable smell of cacodyl. It rapidly attacks indiarubber, and combines immediately with oxygen, without, however, catching fire spontaneously, in this respect differing from dimethylarsine. The production of monophenylarsine from monophenylarsenic acid is described in the same paper.

IN continuing his researches on ammonium amalgam M. Moissan has arrived at some interesting results which he describes in the current number of the *Comptes rendus*. Sodium amalgam was allowed to act upon ammonium iodide in solution in liquid anhydrous ammonia at a temperature of about −39° C. Under these conditions the sodium amalgam reacts upon the ammonium iodide and becomes more fluid, without the formation of any gas. The sodium iodide formed together with the excess of sodium were then removed by liquid ammonia at a temperature of −40° and then with ether at −80° C. The solid ingot thus produced was then placed in a tube kept at −90° and connected with a mercury pump. It was found that a perfect vacuum could be maintained in the apparatus without any gas being given off by the ingot. The temperature was then allowed to rise, when a mixture of ammonia and hydrogen gases in the proportion of two of the former to one of the latter was given off. All these facts would appear to point to the conclusion that the radical NH_4 is actually present in the metallic mass prepared at −39°, but M. Moissan believes that this is not really the case, there being a possibility that a metallic ammoniacal hydride is formed. He has found that when sodium amalgam reacts with a solution of ammonia in water, there is a slow evolution of gas without foaming. If, however, sodium hydride in solution in sodium amalgam is placed in the same liquid, there is at once a foaming mass produced, which may last for two or three days. Further experiments are promised in this direction.

THE additions to the Zoological Society's Gardens during the past week include a Chacma Baboon (*Cynocephalus porcarius*) from South Africa, presented by the Lord Dunleath; a Toque Monkey (*Macacus pileatus*) from Ceylon, presented by Mrs. de Koop; a White-crowned Mangabey (*Cercocebus aethiops*) from West Africa, presented by Mr. S. J. Dean; a Grecian Ibex (*Capra aegagrus*), South-East European, presented by Mr. B. A. Isaac; a Common Water Buck (*Cobus ellipsiprymnus*) from South Africa, four Viscachas (*Lagostomus trichodactylus*) from Buenos Ayres, a Black-headed Oriole (*Oriolus melanocephalus*), an Orange-headed Ground Thrush (*Geocichla citrina*), two Indian Shamas (*Cittocincla macrura*) from India, deposited.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN DECEMBER.

Dec. 3. 13h. Juno in conjunction with moon. Juno 0° 14′ S.
4. 22h. Venus at greatest elongation, 47° 15′ E.
9. 9h. Uranus in conjunction with the sun.
11–13. Epoch of the Geminid meteoric shower (radiant 109° + 33°).
13. 23h. Mars in conjunction with Saturn. Mars 1° 18′ S.
14. 6h. 43m. to 7h. 39m. Moon occults β Capricorni (mag. 3·4).
15. Venus. Illuminated portion of disc = ·445.
Mars. Illuminated portion of disc = ·980.
16. 9h. 46m. Minimum of Algol (β Persei).
17. 3h. Mars in conjunction with Jupiter. Mars 0° 52′ S.
18. 7h. 24m. to 8h. 9m. Moon occults λ Piscium (mag. 4·7).
19. 6h. 35m. Minimum of Algol (β Persei).
22. 1h. Sun enters Capricornus. Winter commences.
22. 2h. Neptune in opposition to the sun.
23. 5h. 53m. to 6h. 12m. Moon occults ε Tauri (mag. 3·7).
27. 10h. 42m. to 11h. 50m. Moon occults A^2 Cancri (mag. 5·8).
31. 9h. Juno in conjunction with the moon. Juno 0° 18′ N.

LEONID METEORS, NOVEMBER 1901.—Mr. G. C. Thompson sends the results of observations at Penarth of Leonid and sporadic meteors on the nights of November 14–15 and 15–16. Between November 14, 11.35 p.m., and November 15, 1.55 a.m., four bright Leonids were observed, all exhibiting characteristic green streaks, four probable Leonids, without streaks or train, one of doubtful origin, and four sporadic meteors. On the night of November 15–16 no meteors were observed until after midnight, but between 12.20 a.m. and 12.50 a.m. one bright Leonid was seen, two probable Leonids, and four sporadic meteors.

Mr. J. R. Henry, writing from Dublin, says "there was a distinct display here of meteors from the Leonid radiant on the morning of November 15. During a watch kept from 10.20 to 11.15 on the night of November 14 only three meteors of the first or second magnitude were observed. The first was a fine bolide which passed a few degrees to the right of Gemini towards Leo at about 10.55. The watch was resumed at 12 o'clock under somewhat restricted conditions as regards position, which faced the east. From 1 to 3.30 meteors shot steadily from the Sickle at the rate of about twelve per hour for those of the first or second magnitude. No sporadic shooting stars above the third magnitude were noted in this part of the sky. The brightest meteor, equal to Sirius, was observed at 2.40 a.m. It passed somewhat slowly from the Sickle to a position 20° below Procyon. A brilliant flash illuminated the eastern horizon at 3.30 a.m."

MOTION OF THE GREAT RED SPOT ON JUPITER.—In *Popular Astronomy*, vol. ix. pp. 448–490, Mr. W. F. Denning discusses the observations secured of the position of the great red spot during the period 1894–1901, illustrating the result by a curve showing the drift in longitude of about 50° in that time. An observation made on 1901 September 5 is interesting from the fact that it was exactly seventy years after that of 1830 September 5, when H. Schwabe at Dessau first drew the hollow. During this interval of 2,208,980,280 seconds the planet has made 61,813 rotations, giving a mean period of 9h. 55m. 36·56s.

The observations at Bristol have mostly been made with a power of 312 on a 10-inch reflector.

PRELIMINARY INVESTIGATION OF THE DIAMETER OF MARS.—Prof. T. J. J. See, in continuation of his work on planetary diameters, gives the results of old and new measures of the disc of the planet Mars in *Astronomische Nachrichten*, Bd. 157, No. 3750. The measures published from 1651-1901 are tabulated and divided into two categories, according to their being determined with the wire micrometer or the heliometer. The values obtained in these two ways are markedly different, the mean diameter from the wire micrometer being 9·678, that from the heliometer 9·338, at mean distance. This discrepancy has been usually attributed to irradiation. A considerable number of experimental trials have been made at the Washington Observatory in order to get a trustworthy value for the correction due to this cause, and the results obtained from a recent series of determinations, using liquid screens in the eyepiece, are given. The polar diameter of the planet is thus estimated as

$$9''\cdot222 \pm 0''\cdot013$$
$$= 6687 \text{ km.} \pm 10 \text{ km.}$$

Assuming an oblateness of 1 in 200, the equatorial diameter may be taken as $= 9''\cdot30 = 6743$ km.

DEFINITIVE ORBIT ELEMENTS OF COMET 1899 I.—Mr. C. J. Merfield, of Sydney, has computed the definitive elements of the orbit of this comet from the available observations during the period 1899 March 4–August 10.

Elements.

Epoch of osculation 1899 March 12.
T = 1899 April 12·978010 G.M.T.

$$\left.\begin{aligned} \omega &= 8^\circ\ 41'\ 46''\cdot48 \\ \Omega &= 24\ 59\ 59\cdot93 \\ i &= 146\ 15\ 30\cdot29 \end{aligned}\right\} 1900\cdot0$$
$$\log q = 9\cdot5139795$$
$$\log e = 0\cdot0001521$$
$$e = 1\cdot00035029.$$

In the course of the article many hitherto isolated descriptions of the varying appearances of the comet during its period of visibility are brought together. Throughout March 1899 the comet appeared as a nebulous mass 4′ or 5′ of arc in diameter, with a central condensation. After perihelion passage many changes commenced to be presented. Prof. Perrine, at Lick, observed the nucleus to be double, and obtained measures of the components, the distance between them increasing from 12″–18″ of arc during the period 1899 May 11–14. This feature was later confirmed by Prof. Barnard, who measured the two nuclei with the Yerkes refractor, and found the separation to increase from 29″–38″ of arc during 1899 May 20–23. This increasing distance would appear to be partly due to an actual separation of the two portions of the nucleus, but this has not yet been examined sufficiently to be decisive.

On 1899 June 5 a considerable increase of brightness was noticed by many observers, the nucleus being estimated by Dr. Hartwig to be 9·5 magnitude and the whole comet about 5·0 magnitude, the diameter of the coma being about 12′ of arc. Dr. Schorr recorded that the nucleus appeared to be excentrically situated. (*Astronomische Nachrichten*, Bd. 157, No. 3747-48.)

THE CHEMISTRY OF THE ALBUMINS.

THE albumins, using this term in its widest and most general sense, form almost the last of the great natural groups of substances which have hitherto presented an impenetrable front to the attack of the synthetic chemist. With the progress of organic chemistry, some, at all events, of the alkaloids, the sugars and the glucosides have yielded up their secrets of constitution and configuration so fully that their synthetic preparation has crowned the labours of the investigator and confirmed the deductions he has drawn from a study of the reactions and transformations of the products found in nature. But the chemistry of the albumins, in which lie locked up the secrets of animal and vegetable growth, of health and disease, perhaps even of life and death, has not yet progressed beyond the preliminary stages of investigation—the establishment of criteria of purity and methods of separation, and the study of reactions and decomposition products. These first studies have, indeed, added much of great value and importance to our knowledge of this supremely interesting class of compounds, but the very complication of the results obtained has produced rather a feeling of mental bewilderment than one of increased insight and comprehension.

In these circumstances the report of a lecture by Prof. Kossel on the "Present Position of the Chemistry of the Albumins," which is contained in a recent number of the *Berichte*, will be of special interest to both physiologists and chemists. The lecture forms one of that series of addresses on special branches of chemistry, delivered by the foremost of those engaged in active work upon them, which has been for some years one of the most valuable and attractive features of the activity of the German Chemical Society, and one well worthy of imitation.

From the admirable account of the subject there given, it appears that in several directions important advances have been made, and we propose here to indicate shortly the nature and tendency of these, after first pointing out some of the difficulties which have not yet been overcome.

In the first place, no entirely satisfactory criterion of chemical individuality has yet been found for the albumins, all the prevailing methods which the chemist has been forced to employ for their purification and separation—precipitation by various reagents, coagulation, differences of solubility, and even crystallisation—being pronounced insufficient to guarantee the individuality of the product. This is due partly to the colloidal nature of these substances, a property which is most probably conditioned by their enormously high molecular weight, and partly to their great tendency to form loose compounds with other substances, and especially with such as occur along with them in the tissues of plants and animals.

A second difficulty lies in the great number of different substances belonging to this class which have been prepared, even with the imperfect methods at present at our command, and in the bewildering complexity of the products of decomposition obtained from many of them by such simple means as hydrolysis.

One instance may suffice to illustrate this point and at the same time serve as an enumeration of the various chemical groups obtainable from a complicated member of the class. Certain nucleoproteids yield on hydrolysis the following products, each of which represents a different group in the molecule of the mother substance:—arginine, histidine, lysine, leucine, asparaginic acid, glutamic acid, pyrrolidinecarboxylic acid, the purine bases, thymine, phosphoric acid, two groups containing sulphur, and separate groups yielding furfuraldehyde, skatole and lævulinic acid; most of these groups are, moreover, with great probability contained several times over in a single molecule.

Fortunately, however, all the albumins are not as complicated as this, and it is by the discovery of simpler members of the class and by a quantitative study of the products of their decomposition—researches almost entirely due to Kossel and his coworkers—that the most substantial advance of recent years has been made. These, the least complex albumins yet known, have been obtained from the spermatozoa of certain fish and have received names denoting their origin, *e.g.* salmin, sturin, clupein, &c. They possess strongly basic properties, turn red litmus blue and form salts with acids, yet unite with this chemical activity the high molecular weight and colloidal properties of the albumins, and have hence been termed the *protamines*. Their comparative simplicity is, however, shown by the nature of the products formed from them by hydrolysis.

The more familiar and complex members of the group, such as casein or egg-albumin, yield on hydrolysis a large number of different products, which may, however, be grouped in four main classes:—

(1) A compound capable of yielding urea. This is invariably found in the form of *arginine*, or guanido-amidovaleric acid, a compound which may be regarded as at the same time a derivative of urea and of diamidovaleric acid.

(2) The diamido-acids, at least three members of which have been recognised, including the group contained in arginine.

(3) The monamido-acids, ten or eleven different acids having all been found.

(4) A number of other products such as ammonia, furfuraldehyde, pyrrolidinecarboxylic acid, humus-like substances, &c.

The proportions in which the representatives of these classes are produced vary greatly for the different albumins, casein, for example, yielding very little arginine (about 5 per cent.) and a large proportion of monamido-acids (75-85 per cent., including at least three or four different acids).

Now the simplest protamines, of which salmin may be taken

as a typical representative, are found to be almost entirely converted by hydrolysis into two compounds: nearly 90 per cent. of their nitrogen, or 84 per cent. of their actual weight, is found as arginine (classes 1 and 2) and several per cent. of their nitrogen as monamidovaleric acid (class 3), the nature of the small remaining amount of product being as yet unknown. Basing himself on the qualitative simplicity of these products and the large preponderance of arginine, Kossel proposes, for the purpose of classification, to regard arginine, or rather the group from which it is derived, as the chemical nucleus of the albumin molecule, from which all the albumins may be derived by the addition of other groups. Increase in the complexity of the structure of the albuminous molecule is rendered evident by the appearance of a multiplicity of individual substances in classes 2, 3 and 4 of the products of hydrolysis. Thus sturin, a more complex protamine, yields only 58 per cent. of arginine, together with 25 per cent. of two diamido-acids (lysine and histidine, class 2), and a monamido-acid, the relations by weight showing that in this case four molecules of arginine are produced for one each of lysine and histidine.

A means of passing gradually from the chemical structure of these non-albuminous, ultimate products of hydrolysis back to that of the mother-substances, the albumins themselves, is afforded by the circumstance that the hydrolysis can be so effected, especially by means of the various proteolytic enzymes, that intermediate products, the albumoses and peptones, are formed. These, although certainly simpler in structure than the original albumins, still show the characteristics of the class, and it is the knowledge of their composition that must form the proximate object of research. For this purpose the intermediate products obtained from the protamines, which are known as the *protones*, afford the simplest material, and the results of these researches will be eagerly awaited.

A certain amount of progress has indeed already been made in the examination of the albumoses and peptones derived from the more complex albumins, for it has been shown that certain of the constituent groups of the original molecule are absent from some of the albumoses derived from it, whilst present in others, a proof that the molecule has been divided into dissimilar groups. This is true, for instance, of the tyrosine- and indole-forming groups of fibrin, which are present in protalbumose, but absent from heteroalbumose.

The highest degree of complexity among the albumins is exhibited by the glucoproteids and the nucleoproteids, of the decomposition products of which an illustration has already been given. These appear to be compounds of albumins with other—*prosthetic*—groups, such as the hexoses, hexosamines, purine derivatives, &c., and even inorganic groups like phosphoric acid.

In conclusion, it is pointed out that the old idea of albumin as a substance of fixed and definite properties must be abandoned; it must be recognised that the albumins form a group comprising many substances which differ greatly in structure and properties. In accordance with the general principle of evolution, the aim of the investigator must be to find a chemical system of albumins which, progressing from the simplest up to the most complex member, shall reveal to us the true nature of these mysterious substances.

SCOPE AND FUNCTIONS OF MUSEUMS.[1]

IT is my lot, as director of the Natural History Museum in London, to have my attention very closely directed to the question as to what a public museum should aim at, what should be its objects, and how it should be organised for effecting them. I am inclined to think that few people ever ask themselves why we have museums, how they came to exist, and why public funds are expended on them, both by municipalities and by the State.

The word "museum" is in itself a strange one, which has acquired a special and restricted meaning. In Germany a club for music and discussion of art and science, with the maintenance of a library, and sometimes with a beer garden attached, is often called a "museum," much as we call a club an Athenæum. In England and in France the word museum—by a process which I cannot trace—has within the past two centuries become applied to what used to be called a "cabinet of curiosities (or rarities) of art and nature." You will find that all our great museums, and many local museums, owe their origin to such cabinets or collections of rarities. Thus the British Museum originated with the collections of Sir Hans Sloane, and the Ashmolean and University Museums at Oxford had as their nucleus the collection of miscellaneous objects of interest formed by the Cornish antiquarian and naturalist Tradescant. These collections were always, in the first instance, of the most miscellaneous kind. An elephant's skull, a glove worn by Queen Elizabeth, a thunderbolt and a cannibal's spear are samples of the objects placed in these collections side by side. When such "cabinet" or "collection" of rarities attained to celebrity, its fortunate possessor (in the eighteenth century) made a habit of bequeathing it, or possibly selling it, to some public body, so that it might be maintained for ever as a show for the delight and instruction of future generations of men. That seems to be the origin of public museums, and it goes on repeating itself even at the present day. A collector gives his collections to a public body, to a city Corporation, or to the State, or to a local Board, or a Committee; the charge is accepted, and another "museum" is instituted.

Whilst it is certainly ungrateful to look a gift horse in the mouth, or to scrutinise too closely the collection bequeathed or presented by an enthusiast, yet it is a fact that this kind of spasmodic and unconsidered foundation of museums is inconvenient at the present day. We have now had some experience of museums, and a little reflection will show us what is the good and what is the bad of these miscellaneous collections, and what any public body should aim at when accepting or taking charge of a museum.

As distinguished from a library or a picture gallery, a museum, as we understand the term at the present day, is a repository in which are partly exhibited, partly stored, objects, tangible things, which are neither books nor pictures, but are actual relics of antiquity or samples of animal, vegetable or mineral structure of such a nature as to extend or to illustrate our knowledge of the history of man or of the natural world.

It seems to me—if I may go at once to the point without further preface—that a public museum, whether it be that belonging to a municipality such as ours here in Ipswich, or one belonging to the State, such as the British Museum, should have two distinct and recognised objects, the germ of which we can trace in the old collectors' cabinets of rarities of nature and of art. In the first place, such a museum must aim at collecting and preserving for the study and information of all men, but especially of those who live near it, the records of antiquity and of natural history in the locality of which it is the centre. A great part, even a half of the space of a museum building, should not be occupied by exhibition cases, but contain cabinets and cases in which precious things are preserved ready for the study of those who are willing to give time and skill to their study. But the second great object of a museum (present also in the old collectors' minds) is to exhibit in the most perfect and attractive way, in public show galleries, to all who choose to come and see, the most interesting, beautiful and instructive of the things in its possession, and especially to show such things as will readily excite an interest in the study of archæology and natural history amongst the inhabitants of the town or city in which the museum is situated.

There is a third use of museums, and the collections in them, which ought, I think, to be very carefully separated from the two I have just mentioned. A student of text-books, preparing for examination and carefully pursuing his educational studies, requires specimens to handle and to manipulate closely. A collection suited for his purposes is quite different from the exhibition-collection addressed to the larger public, and ought never to be confused with it or with the record-collection of a local museum. These strictly collegiate and technical collections ought to be placed in colleges and schools, and kept apart from the more striking and generally interesting collections. When the public is admitted to such students' collections a great mistake is made. The ordinary man is bewildered and wearied by such minute details as are fit for the academic student, and becomes so bored and exhausted that the word "museum" has ever after an evil sound in his ears. You cannot appeal artistically and effectively to the casual well-meaning visitor to a museum if you show him endless rows of obscure objects, which nevertheless have value for the special student. My opinion is very strong that these two kinds of

[1] Abridgment of an address delivered at the opening of a new wing of the Ipswich Museum on November 8, by Prof. E. Ray Lankester, F.R.S., president of the Museum.

collections should be kept far apart, and I doubt very much whether the State or the municipality should undertake to set out and exhibit students' collections. They inferere, in my judgment, with the two great combined objects of a "public museum," namely, first to preserve objects of permanent interest and value, especially those of the locality; and, secondly, to excite in the general public—the ratepayers who pay for the whole affair—a pleasurable and intelligent interest in the purposes of the museum by the exhibition of a limited number of fine specimens, not crowded together, but well set out and beautifully housed and cared for.

Nothing is so hostile to the true spirit and purpose of a public museum as to exhibit in it dirty, ill-mounted, mean and contemptible specimens. Next to this, nothing is so bad for a public museum as to crowd specimens in the cases, so that none produces its due effect. After this, in order of harmfulness, come illegible and careless labelling and bad classification. Local museums suffer from want of funds to pay for good cases and good setting out of specimens, and for the printing of good labels. Still more, perhaps, do they suffer for want of funds to pay for the intelligent services of a curator. But in regard to this, I believe that when there is a great deal of voluntary service and personal help given in a town, with the object of making the museum a worthy show of which the town can be proud, there need not be much difficulty in paying the salary of a curator. I must, however, tell you that he ought not to have other work to do, if you wish him to keep your museum in a state of efficiency and beauty.

Perhaps one of the greatest difficulties which local museums suffer from is the ill-considered generosity of local collectors. I know of several museums which are rendered more or less ridiculous by the worthless collections of ill-stuffed birds or other such objects, presented and, I regret to say, accepted by well-meaning committees or trustees. No collection should ever be accepted with conditions attached to it unless money is also given for carrying out those conditions, and, as a rule, no collection whatever should be accepted *en bloc* from a private donor. The friends or relatives of a deceased collector very often seem to think that a public museum is a place where rubbish may be shot. This should not be allowed. The managers of a museum, with the advice of their curator, should have definite purpose and intention, and should know what they want and try to obtain it by gift or purchase. But they should not allow themselves to be the instruments of vanity or sentiment, and should never allow their museum to become a receptacle for rubbish, no matter by whom it is offered.

If I might venture to apply some of these remarks to the Ipswich Museum, I should say the Museum ought first of all to provide an absolutely safe repository for objects of antiquity found in the neighbourhood, extending from flint implements and Roman pots to old china, brass-work and wood-carving; also for the skins of rare birds and mammals taken in Suffolk, and for the fossils of the wonderful Red Crag, which is unique as a geological phenomenon in England. Such things should be cared for, labelled, and preserved with the greatest care. The best of these things should be exhibited in the best possible cases, with ample space, and in your best rooms, fully labelled and explained. It forms *the* local collection. But besides these, and as illustrating them and the sciences with which they are connected, you should have as many really fine examples of birds and mammals, of fishes, shells, starfish and corals as your space and your funds allow you to show in a really beautiful and attractive way. These also should be fully labelled and explained. That is a *sine qua non*. They should comprise such things as the skeleton of the horse and the man, side by side; of the lion and the cat; and a few other perfect and well-chosen examples of the skeletons of animals. Then you should have the whole or parts of recent elephants to illustrate the Mastodon of the Crag and the Mammoth of the river-bed of the Orwell. The skeleton of the recent bull should be compared with the extinct ones whose bones are dug up in the local gravels. Then a glimpse should be given of some of the utterly strange extinct monsters whose skeletons are preserved in larger museums, from which you can obtain complete casts, scarcely distinguishable from the original specimens.

I do not think there is any advantage in setting out on perches in the glare of daylight, which soon destroys their colour, a complete set of British birds. If you have these and their eggs, they should, excepting a few of the more striking, be unmounted and kept in drawers.

In such a Museum as this, plants, of course, will not be neglected. A herbarium can readily be formed and kept for reference and record. But for your exhibition cases there are many most interesting features concerning the seedlings, early and later growth, and changes of our native trees, which form most striking and instructive exhibits. In an agricultural county a set of models illustrating the life-history of wheat, such as has lately been set up in the Natural History Museum, would be greatly appreciated. Further, let me say that there is a no more beautiful and interesting class of objects for a public museum than really fine crystals and minerals of various kinds. The history of agates, and of the carnelians and other pebbles from the Felixstowe beach would form a delightful and most attractive case in the Ipswich Museum. But in no instance should there be a mean or dirty or ill-considered specimen in any one of your glass cases.

I think that the whole of one of the larger rooms in such a museum should be kept shut up and used for placing cabinets and for storing those specimens in glass cases with which it is not desirable to try the patience of the general public. They should be accessible on proper application; but why show all your doubtful specimens, your obscure though important fragments, your faded skins of birds and mammals to the public? It is not always right to destroy unsightly specimens, but it is never right to offend and disappoint the innocent visitor to a museum by thrusting them under his eyes. He wishes to be pleased, to learn something—not too much—but still something of natural history. You may lead him on by judicious exhibition to enthusiasm and serious interest in science: then he will be able to tolerate the sight of your sick specimens, but you gain a bad reputation for museums if you let your visitor be disgusted at the very first by incongruity and neglect.

A county museum is not a place for children or school-teaching: it is not Noah's Ark or Madame Tussaud's waxworks, but a place for the delight of grown-up men and women. It should be full of the things which are the pride of those who care for the history and natural life of their countryside, and just as you do not use a picture gallery to teach the elements of drawing, but for the enjoyment of fine pictures, so your county museum must be for the enjoyment by your grown-up, educated people of the rarities of nature and of art, and not for the cramming of schoolboys and schoolgirls.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The curators of the University chest have been authorised to spend 1050*l*. in erecting a new chemical laboratory over some of the existing rooms.

Prof. E. B. Tylor delivered a public lecture on November 22 upon totems and totemism, with special reference to the magnificent totem-post from British Columbia which he has recently presented to the Pitt-Rivers Museum.

Brasenose College has elected the keeper of the Ashmolean Museum to an *ex-officio* fellowship, which will have the effect of increasing his stipend by 100*l*. a year and augmenting the income of the Ashmolean Museum and the University Galleries by the same sum.

The 229th meeting of the Junior Scientific Club was held on November 20; a paper was read by Dr. Collier on "Health and Athletics," and Mr. A. T. V. Sidgwick read a paper on "Acetone Di-propionic Acid."

MR. E. H. GRIFFITHS, F.R.S., Fellow of the Sidney Sussex College, Cambridge, has been appointed Principal of the University College of South Wales and Monmouthshire in succession to the late Mr. Viriamu Jones.

THE first number of the *London University Gazette* has appeared, and is largely taken up with a statement of the constitution of the reorganised University and the conditions under which the work is now being carried on. The text is given of an address sent to Prof. Virchow on his eightieth birthday, and of one to Yale University upon the occasion of the recent bicentennial celebrations.

A COMMENDABLE characteristic of the Calendar of University College, London, is the list of original papers contributed by members of the scientific departments of the College to various

societies and publications. The list contains nearly one hundred papers as the record of activity during the College year 1900–1901, and it is a better testimony to the work carried on than many successes at examinations. A similar statement of investigations made in the laboratories of the Royal College of Science and the Solar Physics Observatory during the session 1899–1900 will be found in the recently-published report of the Board of Education, vol. iii.

SCIENTIFIC SERIAL.

American Journal of Science, November.—On the effect of temperature and moisture on the emanation of phosphorus, and on a distinction in the behaviour of nuclei and of ions, by C. Barus.—On the determination of the heat of dissociation and combustion of acetylene, ethylene and methane, by W. G. Mixter. Acetylene was exploded alone and with oxygen and the amount of heat evolved measured. If acetylene is exploded without oxygen in presence of a small quantity of ethylene, the latter is completely decomposed, and in this way the heat of dissociation can be more accurately determined than by the usual combustion method.—The geological relations and the age of the St. Joseph and Potosi limestones of St. Francois County, Missouri, by F. S. Nason.—Note on the Cambrian fossils of the Francois County, Missouri, by C. E. Beecher. From the fossils found an extensive area and thickness of sedimentary rocks are definitely placed in the Cambrian. Palæontological evidence as to the nature of these rocks had hitherto been largely wanting.—Discovery of Eurypterid remains in the Cambrian of Missouri, by C. E. Beecher. Description and drawing of *Strabops Thacheri*.—The determination of persulphates, by C. A. Peters and S. E. Moody. An experimental examination of the methods proposed by Mondolpho, Namias, Le Blanc and Eckhardt, Grutzner and the author. The process of Le Blanc and Eckhardt, the oxidation of ammonio-ferrous sulphate in sulphuric acid solution, is recommended as being simple, rapid and convenient.—Studies of Eocene mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman. A continuation of previous papers on the same subject.—The Carboniferous and Permian age of the red beds of Eastern Oklahoma from stratigraphic evidence, by G. I. Adam.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 22.—Prof. S. P. Thompson, president, in the chair.—Prof. W. Cassie read a paper on multiple transmission fixed arm spectroscopes. The simplest form of spectroscope shown consisted of two half prisms silvered on the back, between which a beam of light goes backwards and forwards with a slight upward inclination. The result in dispersing and resolving power is equivalent to direct transmission through a long train of prisms. The collimator and observing telescope are fixed and adjustment is made by a double tangent screw which moves both the prisms. Two other types constructed on a similar principle were described, of which one had one prism and two speculum mirrors, and the other had two refracting prisms and a reflecting right-angled prism. The adjustments of these instruments are simple and their power great. By a small movement of an adjusting screw the observer can produce great changes of dispersion by passing from one to another of the series of spectra which are produced. The author in reply to questions said that with an ordinary Bunsen burner sodium flame a series of about five spectra is easily observed with dispersion equivalent to direct transmission through ten full-sized prisms. The loss of light at the reflections limits the number of transmissions that can be used; but he believed that no other spectroscope with only two prisms would give dispersing power and resolving power in any way approaching the instrument described.—Prof. W. Cassie then read a paper on the measurement of Young's modulus. The apparatus described consisted of a horizontal needle (a bar of large moment of inertia) supported by a bifilar suspension made of the wire of which the stretch modulus is to be measured. The periods of the pitching, rolling and bifilar oscillations of this system are observed, and an expression for the stretch modulus is obtained which involves no measurements except the weight of the needle and the periods of oscillations. The necessary adjustments, and the means of eliminating residual errors of adjustment, were described for two forms of the apparatus. One form also affords a simple means of statical measurement by hanging a small weight on the needle at measured distances from the centre, calculating the difference of tension produced in the wires, and observing with a mirror and scale the consequent dip of the needle.—A paper entitled "Notes on Gas-Thermometry, Part ii.," by Dr. P. Chappuis, was read by Dr. Harker. Messrs. Holborn and Day have published recently in a research on the air thermometer the results of a new determination of the expansion of Berlin porcelain between 0° and 1000°. The author has already drawn attention in a former note to the fact that part of the divergence found between the results of Callendar and Griffiths and of Harker and himself for the boiling-point of sulphur may be attributed to the uncertainty in the values assumed for the expansion of porcelain. In the present paper the author examines the way in which their results would be modified by the introduction of the dilatation deduced from the experiments of Messrs. Holborn and Day. It follows from the introduction of the new values that the boiling-point of sulphur deduced from experiments with a porcelain reservoir thermometer would be lowered from 445°·2 to 444°·7, a number very close to that obtained by Callendar and Griffiths. In a second part of the paper Dr. Chappuis has recalculated the divergences between the uncorrected nitrogen scale and the theoretical scale, and finds that the difference between these values and those given previously is too small to be of any practical importance. Prof. H. L. Callendar said that he was highly gratified to see that the application of the correction for the expansion of the bulb of Dr. Chappuis' gas-thermometer, deduced from Holborn and Day's results, gave a value, 444°·7, for the boiling-point of sulphur in such close agreement with the value 444°·5, deduced by Mr. Griffiths and himself in 1890. The agreement was really much closer than appeared at first sight, because the remaining difference of two-tenths of a degree in the results was almost exactly accounted for by the scale difference of the constant pressure and constant volume thermometers according to the theory of Joule and Thomson. It was also interesting to remark that the corrected result found by Dr. Chappuis was in very close agreement with that deduced from their own observations by Messrs. Holborn and Day. Dr. Chappuis had not referred in the present note to the work of Bedford on the expansion of Bayeux porcelain, which he had criticised in a previous paper. A comparison of results would show that Bedford's results agreed very fairly, allowing for the difference of material, with Holborn and Day's from 200° to 600° C.; and that both differed from those of Dr. Chappuis between 0° and 80°, when extrapolated, in a precisely similar manner. It was quite possible, as he (Prof. Callendar) had previously suggested, that the expansion of porcelain between 0° and 100° was anomalous. It appeared certain that some anomaly in the expansion at 800° was indicated both in the experiments of Bedford and also in those of Holborn and Day. It was also clear that Dr. Chappuis' results for Bayeux porcelain when extrapolated would agree with Bedford's at a temperature a little above 100° C., or very nearly at the same point at which his results for Berlin porcelain agreed with those of Holborn and Day.

Mathematical Society, November 14.—Dr. Hobson, F.R.S., president, in the chair.—After the ballot had been taken the president announced that the gentlemen whose names were published in NATURE (October 17) were duly elected for the current session. Dr. J. Larmor, F.R.S., propounded a query regarding the recent behaviour of Nova Persei which gave rise to remarks by the president, Dr. Glaisher, F.R.S., and Messrs. Hargreaves, Hough and Lieut.-Colonel Cunningham, R.E.—Prof. Love, F.R.S., communicated two papers by Mr. J. H. Michell, (1) on the inversion of plane stress, and (2) on the theory of Hele-Shaw's experiments on fluid motion, dwelling specially on the latter paper, which also evoked some discussion.—Mr. E. T. Whittaker read a paper on the solution of dynamical problems in terms of trigonometrical series. The president spoke at some length upon the subject and other members joined in a discussion.—The following papers were communicated by the reading of their titles:—Linear groups in an infinite field, Dr. L. E. Dickson; note on the algebraic properties of Pfaffians, Mr. J. Brill; on Burmann's theorem, Prof. A. C. Dixon; the Puiseux diagram and differential equations, Mr. R. W. H. T.

Hudson; determination of all the groups of order 168; Dr. G. A. Miller; an outline of a theory of divergent integrals, Mr. G. H. Hardy; limits of logical statements, Mr. H. MacColl; addition theorems for hyperelliptic integrals, Mr. A. L. Dixon; on the representation of a group of finite order as a permutation group, and on the composition of permutation groups, Prof. W. Burnside, F.R.S.; note on Clebsch's transformation of the equations of hydrodynamics, Mr. T. Stuart, and linear null systems of binary forms, Mr. J. H. Grace.

Geological Society, November 6.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—Note on a submerged and glaciated rock-valley recently exposed to view in Caermarthenshire, by Mr. Thomas Codrington. This valley was brought to light in building a bridge across the River Towy at Drysllwyn, nine miles above Caermarthen, to which the tide now flows. At the bridge the valley is narrowed to about half a mile. Near the water edge the rock sloped down gradually to 23 feet below summer water-level, and was glaciated in large furrows a foot or more across, and striated blocks of grit rested upon it. About 60 feet farther out into the river rock was not met with till depths of from 34 to 42 feet below summer level were reached, and the rock-surface was found to be sloping towards the south at an angle of from 28° to 18° with a vertical line; it was followed down to between 45 and 56 feet below summer water-level. Scratched stones were again met with in the clay near the rock. The glaciated surface on the northern bank is only 25 feet above sea-level; and the rock-surface is sloping down at a precipitous angle at 8 feet below sea-level at a distance of eighteen miles from the mouth of the river.—On the Clarke collection of fossil plants from New South Wales, by Mr. Edward Alexander Newell Arber. This collection, numbering nearly 2600 specimens of all kinds, including some 80 fossil plant-remains, was presented to the Woodwardian Museum, Cambridge, in November 1844. Among other points discussed is the age of the beds. Such evidence as the few plants in the Clarke collection afford supports Feistmantel's conclusion that the Wianamatta beds are of Triassic age. *Thinnfeldia odontopteroides* occurs in Rhætic beds in South America, and the identification of Rattee's *Salisburia palmata* with the American *Baiera multifida*, and a comparison with the Rhætic *Baiera Steinmanni* of Chile, is a new point in favour of this conclusion. The plants also support Feistmantel's opinion that the Newcastle beds are equivalent to the Permian of Europe. The exact origin and age of the Arowa beds must for the present remain doubtful. In the discussion that followed Dr. Blanford expressed his satisfaction at hearing a paper read before the Geological Society in which the Palæozoic age of the Australian Coal-Measures was fully accepted on palæontological evidence. For many years the question had been debated between McCoy, backed by all the European palæontologists, Schimper among others, who declared that the Newcastle beds of Australia were Jurassic, on the one side; and on the other, by the geologists of New South Wales, among whom none did more valuable work in proving the Palæozoic age of the Coal-Measures than the Rev. W. B. Clarke, the collector of the specimens described by the author.—On an altered siliceous sinter from Builth (Brecknockshire), by Mr. Frank Rutley.

Zoological Society, November 19.—Mr. William Bateson, F.R.S., vice-president, in the chair.—Prof. E. Ray Lankester, F.R.S., read a memoir on the new African mammal, *Okapia johnstoni*. After an account of the history of the discovery of this remarkable animal by Sir Harry Johnston, Prof. Lankester gave a description of its skull and skin, based upon the specimens forwarded to the British Museum by the discoverer, and compared its structure with that of the giraffe and the extinct member of the same family, Helladotherium. The nearest living ally of the okapi was undoubtedly the giraffe.—Mr. Oldfield Thomas read a paper on the five-horned giraffe obtained by Sir Harry Johnston near Mount Elgon. It was shown that, although the horns were unusually developed, the animal could not be specifically separated from the ordinary North-African giraffe, *Giraffa camelopardalis*. This latter was believed to grade uniformly in the development of the horns and other characters into the South-African form, which would therefore be only a subspecies, *G. c. capensis*. On the other hand, de Winton's *G. c. reticulata* (from Somaliland) seemed to be sharply separated, and therefore to be worthy of recognition as a distinct species, *G. reticulata*. With regard to the accessory horns, it was shown that they, or rudiments of them, existed in all male giraffes, even in the southern subspecies. Mr. Thomas believed that these rudimentary horns corresponded, not only to the somewhat similar projections found in Samotherium and the okapi, but also to the large posterior horns of Bramotherium, and perhaps of Sivotherium. If this were the case, it seemed probable that they were the degenerate rudiments of horns which had been large and functional in the giraffe's ancestors.—Mr. J. Graham Kerr read some notes on the genito-urinary system in the male Lepidosiren and Protopterus, in which he gave an illustrated account of the more important anatomical features of the organs. Mr. Kerr dwelt particularly on the presence in both Lepidosiren and Protopterus of very definite remains of a testicular network, and pointed out that the presence in all three Dipnoi of the connection between the testis and the kidney gave greatly increased probability to the view that this connection is a very ancient and primitive feature of gnathostomatous vertebrates. Mr. Kerr also pointed out that the conditions in the Dipnoi shed considerable light upon the relations of testis and testis-duct in the Crossopterygians and the Teleosts.—A communication was read from Mr. Alfred E. Pease, M.P., containing some field-notes on the antelopes obtained during his expedition to Somaliland and Southern Abyssinia in 1900–1901.

Mineralogical Society, November 12.—Dr. Hugo Muller, F.R.S., president, in the chair.—Mr. R. H. Solly, in continuation of his investigations on minerals from the Binnenthal, described baumhauerite, a new sulph-arsenite of lead, $4PbS.3As_2S_3$, which crystallises in the oblique system ($\beta = 82° 42'\frac{3}{4}$); the crystallographic examination of good recently-acquired crystals of dufrenoysite led him to refer this mineral also to the oblique system with $\beta = 90° 33'\frac{1}{2}$; twin crystals of hyalophane from the Legenbach Binnenthal were also described.—Dr. H. Warth contributed a note on the occurrence of gibbsite in the Palni Hills in southern India.—Prof. H. A. Miers gave an account of a visit to the Klondike which he had made last August at the invitation of the Canadian Minister of the Interior. He described the various methods of mining which are in operation this year, and showed a number of photographs illustrating the great changes which have taken place in the mining camp. An account was given of the various conditions under which the gold occurs.

EDINBURGH.

Royal Society, November 4.—The Hon. Lord M'Laren in the chair.—The chairman read an opening statement describing the work done during the preceding session and enumerating the losses the Society had sustained, with special reference to the great loss occasioned by the death of Prof. Tait, who had for many years acted as general secretary.—A paper on variable stars of the Algol type was communicated by Dr. A. W. Roberts. It dealt with the star C.P.D. 41°·4511, whose period of variation of brightness is 1 day 20 hours 30 minutes. The light curve has one well-marked minimum lasting 4 hours 30 minutes, with a diminution 0·85 from the normal brightness, which is steady for the remainder of the period with the exception of a short drop of 0·1 dividing it into two symmetrical parts. These variations of brightness are due to the two stars which form the double system eclipsing one another wholly or partially as viewed by an observer on the earth. From them Dr. Roberts deduces the following elements for the double-star system:—Diameter of each (probably the same), 0·325, the distance between them being unity; inclination of orbit, 6° 43′; ratio of the brightnesses of the two components, 6 : 1; and mean density 0·44 of the sun's density, or about two-thirds that of water. The theoretical light curve calculated from these data agreed exactly with the observed light curve.—Prof. MacGregor read a note on the relation of the density of electrolytes to ionisation, chiefly with reference to certain discrepancies which appeared when the densities were measured and calculated to six significant figures.—Prof. Chrystal communicated a paper, by Mr. J. N. Miller, on an instrument for the mechanical trisection of an angle. A rod OAB is rotatable about the fixed point O; and a second rod PAX pivots on A, and PA is made equal to OA. From M, the middle point of AB, a perpendicular is constructed of convenient length. If O is placed at the vertex of the angle to be trisected, the trisection is accomplished by adjusting the instrument until the point P lies on one side of the angle and the other side of the angle passes through the intersection of AX with the perpendicular to the middle point of AB. The curve

on which the properties of the instrument depend is a unicursal curve of the sixth degree, and Prof. Chrystal showed how, by making a templet in the form of part of the curve, the trisection of a given angle could be easily effected with the use of a pair of compasses.

CAMBRIDGE.

Philosophical Society, November 11.—Mr. W. Bateson, vice-president, in the chair.—The unit of classification in systematic biology, by Mr. H. M. Bernard. The writer described the difficulties he had experienced in grouping the stony corals into genetic groups, and maintained that the time had come when for such unstable groups a new technique was urgently required. The present unit of classification, the only one we had at our disposal, was the species. Hence if these are not discoverable the work is brought to a standstill. His work with the stony corals had suggested to him a geographical method of designating the varying *forms* as the units for work. These forms he proposed to arrange in geographical lines. Upon the chart of each genus thus obtained he proposed to arrange the different structural variations exhibited within the genus, and hoped to find in this way a powerful and searching instrument for morphological study by means of which in time a natural classification may be built up.—An exhibition of fishes and amphibians to illustrate new methods of mounting specimens for museums, by Mr. J. S. Budgett.—Notes on the development of Sagitta, by Mr. L. Doncaster. The paper confirmed O. Hertwig's account of the development in most points, but showed that Bütschli's account of the formation of the head-cœlom was correct. Sections were described showing the temporary obliteration of the cœlom and the origin of the muscles. The genital cells were described, and the origin of the posterior septum between them during larval life. The development of the genital ducts was discussed, and this, together with the mode of origin of the transverse septa and absence of nephridia, led to the rejection of the view that the Chætognatha are connected with Annelids.

DUBLIN.

Royal Irish Academy, November 11.—Prof. R. Atkinson, president, in the chair.—Prof. Charles J. Joly read a paper on the interpretation of quaternions as point-symbols. The author explained a convention by means of which a quaternion may be interpreted as the symbol of a weighted point. He assumes an arbitrary origin, and writing

$$q=(1+\mathrm{OQ})\mathrm{S}q, \quad \mathrm{OQ}=\mathrm{V}q/\mathrm{S}q,$$

he interprets the quaternion q as denoting the point Q at the extremity of the vector $\mathrm{V}q/\mathrm{S}q$ drawn from the origin. The weight attributable to this point is $\mathrm{S}q$—the scalar part of the quaternion—so that multiplication by a scalar leaves the representative point unchanged and merely alters the weight. He gave some examples of applications to projective geometry, and pointed out that the equations

$$\mathrm{S}q(f+f^1)q=0, \quad \mathrm{S}q(f-f^1)p=0$$

represent respectively the equation of the general quadric surface and the equation of the general linear complex, f being a linear quaternion function and f^1 being its conjugate. The equations of the reciprocals of these loci are simply

$$\mathrm{S}q(f+f^1)^{-1}q=0, \quad \mathrm{S}q(f-f^1)^{-1}p=0.$$

The principle of duality presents itself with perfect naturalness, and a quaternion may also be regarded as the symbol of a plane. Thus two objections to the calculus of quaternions have been removed—the want of a point symbol and of a concrete interpretation for a quaternion—and, what is in the author's opinion of much greater importance, the whole field of projective geometry is rendered easily tractable by quaternion methods.—Prof. Joly also read a paper on quaternion arrays. In the previous paper the author employed and extended a most useful but neglected notation of Hamilton's ("Elements," art. 365 [6]) in order to define lines, planes and volumes in terms of two, three and four quaternions or points. In this paper the notation is further extended, and the vanishing of the array with quaternion constituents

$$\left\{\begin{matrix} a_1, & a_2, & a_3 & \ldots\ldots & a_n \\ b_1, & b_2, & b_3 & \ldots\ldots & b_n \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ p_1, & p_2, & p_3 & \ldots\ldots & p_n \end{matrix}\right\} \quad (n \text{ columns, } m \text{ rows}),$$

expresses the possibility of determining n scalars $t_1, t_2, \ldots\ldots t_n$, so that

$$\Sigma t_1 a_1=0, \quad \Sigma t_1 b_1=0, \quad \ldots\ldots \quad \Sigma t_1 p_1=0.$$

The laws of expansion and of manipulation of these quaternion arrays are explained, and it is pointed out that the quotient of a two-row and a one-row array

$$\left\{\begin{matrix} fa, & fb, & fc, & fd \\ a, & b, & c, & d, \end{matrix}\right\} \div \{a, b, c, d\}$$

comprises all the Hamiltonian invariants of the linear quaternion function f—a result easily extended to the case of any number of functions by increasing the number of rows in the first array. As another example of the use of these arrays, if μ is the couple and λ the force of a wrench, the origin being base-point, the invariants of an n-system of screws are at once deducible from the array,

$$\left\{\begin{matrix} \mu_1, & \mu_2, & \mu_3 & \ldots\ldots & \mu_n \\ \lambda_1, & \lambda_2, & \lambda_3 & \ldots\ldots & \lambda_n \end{matrix}\right\}.$$

—Mr. Frederick Purser read a paper on the application of Bessel's functions in the theory of elasticity. This paper attempts to use Bessel's functions in the discussion of the elastic equilibrium of a right circular cylinder. It is shown that the elastic forces and displacements at any point when no bodily forces act can be expressed as the sum of two series, one of which proceeds by products of exponential functions of z and ordinary Besselians in r, the other by products of trigonometrical functions of z with Besselians in r of imaginary argument. The method is also applied to certain cases of applied bodily force, and various practical problems are considered both with a view to approximate solution and as illustrating the St. Vénant theory of equipollence, on which it is conceived the present method throws some light.

PARIS.

Academy of Sciences, Nov. 18.—M. Fouqué in the chair.—On the periods of double integrals in the theory of algebraic functions of two variables, by M. Émile Picard.—On a modification in the mode of use of an electrical thermometer, for the determination of subterranean temperatures at the Museum of Natural History, by M. Henri Becquerel. A description of a new method of applying the thermocouple to the determination of temperature at a distance. A d'Arsonval galvanometer, the deviations of which are proportional to the intensities of the currents, is used, and the scale of this galvanometer is calibrated in degress by direct comparison with the thermocouple and a mercury thermometer. One junction of the thermocouple is then placed in the point the temperature of which is required, and the other in mercury along with a thermometer. Since the deflection of the d'Arsonval is now proportional to the difference of these temperatures, the graduated scale is displaced parallel to itself in such a manner that the zero of the galvanometer coincides with the line indicating the temperature of the junction in the mercury. On closing the circuit the reading on the scale now indicates the temperature of the distant junction.—The study of ammonium amalgam, by M. Henri Moissan (see p. 89).—On the Perseids of 1901, by M. Perrotin. There has been an increase in the number of meteors from the Perseids during the present year. The observations at Nice were somewhat incomplete on account of the weather. On August 10 there was an average of 10 stars per hour, on the 11th, 25 to 30 per hour, on the 12th, 32 were counted during the 40 minutes observations were possible, and only 24 were seen on the two following nights.—Observations of the Perseids made at Athens, by M. D. Eginitis. These stars were seen on the four nights commencing on August 9, and were counted up to the sixth order. About 500 meteors were observed in all, the maximum display being on the 11th, when on the average 31 per hour were seen.—On a manometric differential log, by MM. Emile Raverot and Pierre Belly. The two sides of a manometer are connected to two tubes under the water in the same horizontal plane, one tube opening in the direction of motion of the vessel, the other being at right angles. In the case of the tube in the direction of motion, the pressure depends partly upon the velocity of the vessel and partly upon the variable static pressure due to its depth below the surface of the water. The latter effect is completely compensated by the second tube, and by the introduction of a suitable damping arrangement the readings of the manometer are a function of the speed of the vessel alone. The scale is graduated empirically by runs over a measured distance.—The law of radiation at low temperatures, by M. Compan. A series of experiments were carried out on the rate

of cooling of a blackened ball, the temperatures being measured by means of a thermocouple. The rate of cooling was taken over the ranges 302° to 0° C., 174°·3 to −79°·2 C. and 15° to −182°·5 C., and the experimental values compared with those calculated from the formulæ of Dulong and Petit, Stefan and Weber. The formula of Dulong and Petit was found to apply roughly only between 0° and 200°, that of Stefan covered the whole range from the boiling-point of liquid air to 302°, whilst the formula of Weber does not apply at low temperatures, but for the range 100° to 302° it has the advantage over Stefan's formula.—On the combinations of gold and chlorine, by M. Fernand Meyer. Gold was converted completely into the chloride $AuCl_3$ by the action of liquid chlorine in a sealed tube at 70° C. The dissociation of this pure chloride into AuCl and Cl_2 was then studied, and also the dissociation of AuCl into chlorine and gold. No indication was obtained of the existence of a chloride of gold intermediate between $AuCl_3$ and AuCl.—On dioxyisopropylhypophosphorous acid, by M. C. Marie. A study of one of the three acids obtained by the action of hypophosphorous acid upon acetone. The acid is monobasic, and from its analysis and the fact that it forms diacetyl and dibenzoyl derivatives it is assumed to have the constitution $[(CH_3)_2(OH).C]_2PO(OH)$.—The action of some acid chlorides upon the sodium derivatives of methyl and ethyl acetoacetates, by M. Bongert. Details of the compounds obtained by the action of propionyl chloride and butyryl chloride upon ethyl acetoacetate, and of isovaleryl chloride and caproyl chloride upon methyl acetoacetate.—The oxidation of unsaturated alcohols by contact action; the preparation of vanillin, by M. A. Trillat. The vapours of the alcohols mixed with air are submitted to the action of a hot platinum spiral. Allyl alcohol gave 5 per cent. of its weight of acrolein, cinnamic alcohol gave the corresponding aldehyde and isoeugenol gave vanillin. Eugenol gave the same product.—The spermatocyte divisions and chromosome special to the Orthoptera, by M. R. de Sinety.—The blue and green colorations in the skin of the vertebrates, by MM. Camichel and Mandoul. It has been known for some time that the blue coloration of the skin in certain vertebrates is not due to a blue but a black pigment; green skins contain two pigments, black and yellow. A study of these coloured skins with the spectrophotometer shows that there is a complete analogy between these and the phenomena exhibited by turbid media, the curves obtained from skin and from artificial turbid media such as lamp-black and Chinese ink being absolutely similar.—The relation between the liver, skin and hair from the point of view of the pigments and iron, by M. B. Floresco.—The influence of the ingestion of wine on the development of tuberculosis, by M. L. Roos. From experiments made with guinea-pigs the author concludes that there is no reason to suppose that the ingestion of alcohol in the form of wine accelerates the course of tuberculosis.—The formation of pearls and their "diseases," by M. S. Jourdain.—The measurement of the blood pressure in lunatics, by MM. Ed. Toulouse and N. Vaschide. It is shown that there is a distinct connection between the blood pressure and mental troubles; there is also a change in the blood pressure corresponding to different states of the same patient.—A mechanical theory of vision, by M. Antoine Pizon.—An anatomical comparison between grafting, the removal of the heads of buds and annular decortication, by M. L. Daniel.—On chlorophyll assimilation in autumn, by M. Jean Friedel.—On the mica schists, gneiss, amphibolites and green rocks of the schists of the western Alps, by M. Pierre Termier.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 28.

PASTEUR.

The Life of Pasteur. By René Vallery-Radot. Translated from the French by Mrs. R. L. Devonshire. Pp. 628; 2 vols. (Westminster: Archibald Constable and Co., Ltd., 1902.) Price 32*s*.

"L'ŒUVRE de Pasteur est admirable; elle montre son génie, mais il faut avoir vécu dans son intimité pour connaître toute la bonté de son cœur," wrote one of Pasteur's most distinguished disciples who was in daily intercourse with him.

This sentiment, so simply and so eloquently expressed by Dr. Roux, can now, thanks to M. Vallery-Radot, be shared by that larger circle of Pasteur's friends and admirers who, distributed in all quarters of the globe, knew him in his public capacity, but could not have the privilege of being included amongst his intimate associates.

There are, however, few men whose scientific writings reflect the inner life of the man to the same extent as do those of Pasteur, for with Pasteur his work was his life—his religion, and it was inseparably bound up with every action, with every aspiration.

M. Vallery-Radot has enabled us to accompany Pasteur throughout his career, to share alike in his joys and his sorrows, in his anxieties and triumphs, guiding and directing us the while with consummate skill, so that the true proportion of the actions and events which are recorded is maintained in their relation to the whole. As Pasteur's son-in-law, M. Radot has had exceptional opportunities for undertaking this biography, and already we are familiar with his workmanship in that vivid sketch of Pasteur published many years ago, in which the authorship is modestly veiled under the title "l'histoire d'un savant par un ignorant." This little volume was brought out in Pasteur's life-time; since his death we have had M. Duclaux's intellectual appreciation of his master, whom he succeeded as Director of the Pasteur Institute, Dr. Roux's sympathetic personal reminiscences of his great teacher, M. Fleury's impressionist sketch, and in England the volume in the Century Science Series, for which the writer of this notice and her husband are responsible. M. Radot's work differs from all of these inasmuch as he has had access to letters and diaries, note-books and divers documents which were to others inaccessible, and by the judicious use of which the personal element is so happily brought into relief and yet blended so harmoniously with its surroundings.

Of no man could it be more truly said that whatsoever his hand found to do he did it with all his might; the *de minimis non curat* did not exist for Pasteur. As Dean of the new Faculté des Sciences at Lille, for example, despite his passionate devotion to his researches on crystals and molecular dissymmetry, he would forsake his beloved laboratory to take his students round factories and foundries, even organising a tour in Belgium so that they might visit the industries of the country, "questioning the foreman with his insatiable curiosity, pleased to induce in his students a desire to learn."

Later, when he returns to the École Normale as administrator and director of scientific studies, in which office was included such miscellaneous duties as the surveillance of the economic and hygienic management, the responsibility for general discipline, intercourse with the families of the pupils and the literary or scientific establishments frequented by them, we find him noting down as matters for attention "Catering; ascertain what weight of meat per pupil is given at the École Polytechnique. Courtyard to be strewn with sand. Ventilation of class room. Dining hall door to be repaired."

If professors in this country have in the past had but slight encouragement to embark upon research, what would they have said to the position of Pasteur in this respect, who at the École Normale, in addition to such vexatious demands upon his valuable time, had no laboratory, but a garret only in which to carry on his investigations, whilst we hear of him later "building a drying-stove under the staircase; though he could only reach the stove by crawling on his knees, this being better even than his old attic"?

The general state of affairs connected with higher education in France was indeed at that time most deplorable, and Duruy, the enlightened Minister of Public Instruction, whilst sympathising with the lamentable position occupied by science in the country and deeply regretting the penurious policy which stifled its aspirations, was unable to make his voice heard in Cabinet councils, the other ministers, we are told by him, "being absorbed in politics."

Pasteur and Duruy had often discussed the contrast presented by the flourishing young University of Bonn, with its staff of fifty-three professors and vast laboratories for chemistry, physics and medicine, and the Strassburg faculty, with its handful of teachers, hampered in every direction by a policy of deplorable penury. It is not surprising to find Pasteur, in the anguish of his soul, well-nigh crushed by the disasters which overwhelmed his country, bitterly exclaiming in 1870:

"We savants were indeed right when we deplored the poverty of the department of Public Instruction! The real cause of our misfortune lies there. It is not with impunity—as it will one day be recognised, too late—that a great nation is allowed to lose its intellectual standard. . . . We are paying the penalty of fifty years' forgetfulness of science, of its conditions of development, of its immense influence on the destiny of a great people, and of all that might have assisted the diffusion of light."

Again he writes in a pamphlet entitled "Why France found no Superior Men in the Hours of Peril":—

"France has done nothing to keep up, to propagate and to develop the progress of science in our country. . . . She has lived on her past, thinking herself great by the scientific discoveries to which she owed her material prosperity, but not perceiving that she was imprudently allowing the sources of those discoveries to become dry . . . Whilst Germany was multiplying her universities, establishing between them the most salutary emulation, bestowing honours and consideration on the masters and doctors, creating vast laboratories amply supplied with the most perfect instruments, France, enervated by revolutions, ever vainly seeking for the best form of Government, was giving but careless attention to her establishments for higher education."

This crying need of a people was voiced by Pasteur more than thirty years ago, at a time when great national disasters were sweeping all before them; a quarter of a century later these words sound a prophetic note of warning to another nation which, with similar arrogance and similar criminal neglect, has made a fetish of political illusions whilst the very foundations upon which the soul of the people depends have been forgotten or deliberately ignored.

"Is it not deplorable, almost scandalous," exclaims the Minister Duruy, "that the official world should be so indifferent on questions of science?" Would that England had a minister who, whilst sharing such a conviction, possessed the courage to express it! Pasteur with rare prescience was never weary of insisting upon the importance of higher education; "if that teaching is but for a small number, it is with this small number, this *élite*, that the prosperity, glory and supremacy of a nation rest," and we find him again and again returning to the same theme.

M. Radot takes us step by step along the victorious path which Pasteur cleared in the conquest of the most difficult scientific problems of the day. Yet he reminds us that those imaginative people

"who would decorate the early years of Louis Pasteur with wonderful legends would be disappointed; . . . at the Arbois College he belonged merely to the category of good average pupils . . . at the examination for the *baccalauréat ès sciences* he was only put down as *médiocre* in chemistry."

But all this was to be changed, and under the inspiring influence of two such teachers as Balard and Dumas he became a student of chemistry second to none in the enthusiasm for his subject.

His discoveries in crystallography soon won for him a foremost place in the scientific world. In a letter from the great physicist Biot to Pasteur's father we have a charming tribute paid by the aged to the young philosopher.

"It is the greatest pleasure that I can experience in my old age to see young men of talent working industriously, and trying to progress in a scientific career by means of steady and persevering labour and not by wretched intriguing. That is what has made your son dear to me, and his affection for me adds yet to his other claims and increases that which I feel for him."

Biot's friendship for Pasteur, which ripened into a fatherly love and pride in his work, only terminated with his death and was one of Pasteur's most valued possessions.

It will be remembered how Mitscherlich had discovered that the two tartaric acids so familiar to chemists, while apparently identical in chemical composition, in chemical properties, in crystalline form and, in fact, in every known detail, behaved differently in solution towards polarised light. This distinguished crystallographer, unable to detect any difference in these two tartrates, asserted that they were identical in every other particular. Pasteur could not accept this conclusion as to the absolute identity of these substances in face of the fact of their different behaviour towards polarised light, and determined, if possible, to procure some of the inactive tartaric or racemic acid and submit it to an exhaustive examination. But how to procure this racemic acid? Originally obtained in 1820 by Kestner, at Thaun, through a mere accident in the manufacture of tartaric acid, it had suddenly ceased to appear in spite of all efforts to obtain it again. Pasteur's emotion was immense on hearing from Mitscherlich that a manufacturer in Saxony had again produced some racemic acid, and that he believed the tartars employed had originally come from Trieste. "I shall go to Trieste," says Pasteur, in a fever of excitement; "I shall go to the end of the world. I *must* discover the source of racemic acid, I must follow up the tartars to their origin."

Armed with letters of introduction, he starts off on his voyage of discovery and, writes a contemporary, "never was treasure sought, never adored beauty pursued over hill and vale with greater ardour."

How he succeeded in obtaining specimens and in establishing a minute difference in the crystalline structure of these two acids, overlooked by the renowned and experienced Mitscherlich, and how his fundamental discovery of the relationship which exists between crystalline form and optical activity, followed up by a series of masterly investigations, has given birth to that fertile offshoot of chemical science known as stereochemistry, is familiar to all.

The red ribbon of the Legion of Honour was his country's recognition of these brilliant discoveries in the field of chemical science. In the further prosecution of his investigations, Pasteur discovered that if he allowed one of the salts of racemic acid to ferment, the dextro-tartaric component was alone acted upon, which action in his own words he declares to be "the ferments of that fermentation feeding more easily on the right than the left molecules." At this time, when his attention was being arrested by the problems of fermentation in connection with the production of chemical compounds, he was appointed professor at Lille. Difficulties encountered by a local manufacturer in the production of beetroot alcohol induced Pasteur to turn his thoughts more especially to the phenomena of fermentation, and these studies led by a natural sequence to his throwing down the gauntlet to the great Liebig and entering single-handed upon that famous contest with the most brilliant intellects of the day as to the origin of the phenomena of putrefaction and decay.

The current contempt for Pasteur's conclusions may be realised from the following words emanating from the most distinguished chemist of the day. In 1845 Liebig wrote:—

"As to the opinion which explains putrefaction of animal substances by the presence of microscopic animalculæ, it may be compared to that of a child who would explain the rapidity of the Rhine current by attributing it to the violent movement of the numerous mill-wheels of Mayence."

Pasteur relates how, several years later, he visited Liebig in his laboratory, anxious to induce him to acknowledge the truth of his theories; he was received with kindly courtesy, but on endeavouring to approach the delicate subject he had so much at heart, Liebig, "without losing his amenity, refused all discussion, alleging indisposition."

The multiplicity and varied character of Pasteur's researches have been well-nigh forgotten by a generation which almost exclusively associates his name with the

work of his later years—rabies and its prevention. His researches on vinegar, on the diseases of wine, his laborious investigations extending over years which succeeded in disclosing the origin of the diseases in silkworms which had threatened to ruin the silk industry of France, his studies on beer, collected in a magnificent volume covering nearly 400 octavo pages, are but a few of the colossal labours which occupied his mind before he became absorbed in the study of contagious diseases.

At the ripe age of fifty-five we find him devoting himself with all the energy and enthusiasm of youth to the study of pathological phenomena. Various theories as to the origin of anthrax were in the air at the time when Pasteur determined to enter the field. M. Radot gives a most vivid account of these researches and of the hopes and anxieties to which Pasteur was a prey at this time, living as he did in a condition of intense nervous tension and excitement during their progress. Difficulties, however, never deterred, they only served to stimulate, Pasteur. The memoir in which Pasteur and his assistants communicated their successful investigations on anthrax and septicæmia to the Academy of Sciences is famous, not only on account of the manner in which they mastered the etiology of these diseases, but also for the extreme fertility and originality of the ideas and experiments which it records. Having established the identity of the virus he set to work to discover a means of combating its action, and thus he was led to those epoch-making researches in the domain of immunity which were to succeed in converting a virus into a vaccine—a malignant foe into a beneficent friend—and which have made the name of Pasteur a household word revered in the remotest corners of the globe.

M. Radot, besides giving us a faithful and fascinating history of Pasteur's scientific life and aspirations, has with the delicate touch of a master revealed the inner life of this great genius, with rare subtlety indicating the essential character of the man who,

"absorbed as he was in his daily task, yet carried within himself a constant aspiration towards the ideal, a deep conviction of the reality of the infinite and a trustful acquiescence in the mystery of the universe."

No one who reads Pasteur's speeches can fail to be struck by the lofty tone which pervades them; he sought always the highest and scorned to touch what was base; his deep religious sense communicated itself to all who were brought in contact with him, from the most exalted in the land to the poorest student who came to work under his guidance.

In one of those public utterances which in his declining years became so rare and so eagerly sought for he tells us:

"Our only consolation, as we feel our own strength failing us, is the consciousness that we may help those who come after us to do more and to do better than ourselves, fixing their eyes as they can on the great horizons of which we only had a glimpse."

This is the keynote to his life, embodying the same passionate desire to help others which stimulated him from his earliest years, but mellowed by the ripeness of advancing age, and the consciousness of a life fast drawing to a close, the burden of which was soon to be laid aside.

G. C. FRANKLAND.

A MANUAL OF MEDICINE.

A Manual of Medicine. Edited by W. H. Allchin, M.D., F.R.C.P. Lond., F.R.S. Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. iii. *Diseases of the Nervous System.* Pp. x + 417. (London: Macmillan and Co., Ltd., 1901.) Price 7*s.* 6*d.* net.

THE third volume of Dr. Allchin's "Manual of Medicine" is well up to the standard of its predecessors, in fact, if anything, may be regarded as rather exceeding it. Here, in 417 short pages, the student of medicine has at his command a complete and up-to-date book upon that ever-increasing domain of medicine, nervous disease. The difficulty of editing must in this volume almost have reached its maximum. When we come to consider the enormous mass of literature which has accumulated since even the publication of the last standard book upon this subject, we may perhaps appreciate the great difficulty of compressing our compendious knowledge upon nervous disease into what may, without forcing language, be called a manual. In these circumstances we can hardly expect theories to be discussed *in extenso*, or ample polemic justice to be done to controversial matter. The book is filled with terse fact, and if its readability suffers somewhat on this account, its value to the student is proportionally increased.

With the space at our command we must content ourselves with indicating rather than describing the contents of the book. Even to those out of touch with the burning problems of nervous disease, and only generally interested with the physiology of the nervous system as a part of biology, it will be manifest that the recent progress in histological method, the product of increased knowledge of bio-chemistry, has profoundly modified our conceptions of the constitution of the nervous system and also neuro-pathology.

In an introductory chapter Prof. Sherrington deals with the physiology of the nervous system in a most lucid and wonderfully succinct manner. This chapter is followed by one contributed by Dr. Aldren Turner upon the general pathology of the nervous system. Dr. Turner points out that the adoption of the conception that the nervous system consists of a series of neurons necessarily precludes us from continuing to divide affections of the nervous system above the foramen magnum from those below. The only true system of classification must be one based upon the neuronic systems primarily involved. It must, however, be admitted that a given morbid process need not necessarily confine itself to one neuronic system, but may simultaneously implicate two or more. Several other articles are contributed by the same author. The one on focal diagnosis is especially to be recommended.

With the beer-poisoning epidemic fresh in our memory we naturally turn to the article on peripheral neuritis, which is written by Dr. Purves Stewart. The different varieties of neuritis are well described, the author wisely abstaining from controversial matter. Dr. Ormerod contributes articles upon the spinal cord and its membranes and the muscular dystrophies.

The volume concludes with a most instructive and

beautifully illustrated article on medical ophthalmology, by Dr. James Taylor, and one on the medical applications of Electricity, by Dr. Bertram Abrahams.

Dr. Allchin's third volume is, in our opinion, highly to be recommended. We know of no book in the language upon this subject which will be more worth the student's, and indeed the practitioner's, while to read and to possess.

F. W. T.

PRACTICAL MATHEMATICS.

Practical Mathematics for Beginners. By Frank Castle, M.I.M.E. Pp. ix + 313. (London: Macmillan and Co., Ltd., 1901.) Price 2*s*. 6*d*.

THIS little book deserves the title of Practical Mathematics better than any work that we have seen. The subjects dealt with are arithmetic, plane geometry, algebra, mensuration and analytic geometry. The chapters on arithmetic deal with those operations in which this subject is most nearly related to algebra—such as the theory of fractions, ratio and the extraction of the square root. The part on geometry is strictly limited to constructions with rule, compass, &c., and explains the use of simple and diagonal scales; it is in no sense a course of deductive geometry such as we have in the books of Euclid. The part of the book dealing with algebra is more extensive, but still very elementary; it does not, for example, include a discussion of quadratic equations, although it shows how a quadratic expression in x can, in very simple cases, be resolved into factors. While noticing this part of the book we may point out some corrections which should be made in the next edition. Thus, in p. 76, where it is proposed to resolve $x^2 - 9x + 20$ into factors, we find the statement, "Hence $x = 4$, or $x - 4 = 0$ is a factor." The beginner should be put on his guard against such a loose mode of expression. In the next example on the same page we find, "Next put $x = +5$, and it is found to be a factor." The factor referred to is $x - 5$. In p. 77 we have the incorrect expression, "When required to add, subtract or compare fractional expressions, it is necessary that they shall all have a common denominator." In p. 88, g is described as 32·2 "feet per second" instead of 32·2 "feet per second per second," which the majority of mathematicians have at last been forced to acknowledge as the only correct mode of speaking.

These, however, are minor blemishes which are very easily removed.

It is a cardinal aim with the author to make all his examples illustrative of questions relating to various branches of physics, and for a certain class of students (those who have already come into contact with such practical matters) this is a very good plan, because it enlists the interest of the learner in convincing him that he is applying his mathematics to something real. It is doubtful if the plan has as much value for the ordinary schoolboy who is, under our precious system of education, a complete stranger to everything in the domain of physics. Hence such questions as that in example 5, p. 88, relating to the arrangement of a number of Grove's cells, will not convey much meaning to any but students of physics. There are useful little chapters on logarithms, showing their use and illustrating several things in which beginners are very apt to make mistakes. After this we come to an explanation of the slide rule and its applications; and the remainder of the book is that which most entitles it to the name of Practical Mathematics, this portion being of value to the student who wishes to be able to apply his pure mathematics to the representation of physical results. Here there is a great deal of graphic work done by means of squared paper, and a considerable portion of the analytic geometry of right lines, circles and higher curves is expounded, the accompanying illustrations being all drawn from physics. The fundamental notions of the differential calculus are very well and simply explained by this same system of plotting on squared paper; and the ease with which the processes can be followed and understood even by beginners who have nothing but a knowledge of arithmetic and elementary algebra to go upon shows that, in our ordinary course of mathematical teaching, the differential calculus is very unnecessarily postponed—that, in other words, our mathematical course for beginners should be made eclectic in character, a portion of any subject being introduced when the mind of the student is in a state to understand it. Our present system is essentially different; we feel constrained to finish each subject before beginning another, although the finish of one subject may be much more difficult than the preliminary portion of that which is postponed; and we thus lose sight of the fact that our present divisions of mathematics are only artificial, and that mathematics is, in reality, one connected whole.

In the part of the work dealing with mensuration two planimeters are described—the Hatchet and Amsler's.

The work gives an excellent epitome of the various branches of mathematics dealt with, and it will serve as a store of very good exercises in elementary methods for all students who desire to make a practical use of their mathematical knowledge in picturing the relations between various physical quantities.

OUR BOOK SHELF.

Memorial Lectures delivered before the Chemical Society, 1893–1900. Pp. 560. With fourteen portraits. (London: Gurney and Jackson, 1901.) Price 7*s*. 6*d*..

THE Chemical Society has done an important service to chemists and to students of chemistry by collecting these memorial lectures into one volume, and issuing it under conditions which render it accessible to readers of whom some may not be Fellows of the Society and consequently have not enjoyed the advantage of hearing the lectures when delivered or of reading them in the pages of the *Transactions*.

The lives of the men whose work and achievements are commemorated in this volume link us with the now long-distant past, and remind us of the immense strides which have been made in consequence of their discoveries and the discoveries of their contemporaries since the days when Berzelius and, later, Liebig were the dominant authorities. They remind us of the great and almost sudden advance which was accomplished between 1850 and 1865, when the modern system of atomic weights, definite ideas of valency and constitutional formulæ were finally established. The student who aspires to understand by what methods and with what laborious effort the greatest degree of scientific accuracy is alone attainable must read about the work of Stas on atomic

weights. If he wants to know how physical ideas of the constitution of matter and the nature of electrical charges are applied to chemical problems he will read Fitzgerald's lecture on Helmholtz. If he looks for the story of Pasteur's wonderful scientific career and how the chemist applied his chemical experience to the difficult problems of disease and life he will find it admirably told by Frankland in this volume. There are fifteen of these essays in the book, and each possesses an individuality of its own and in general a very high standard of literary quality is reached.

It must, of course, be admitted that the volume does not give the whole history of the progress of chemistry during the last half century, for of course these lectures relate only to deceased *foreign* members of the Chemical Society. The work of Williamson, Odling, Frankland sen., Perkin, Gladstone and Crookes, for example, is only incidentally referred to, for happily these Fathers of Modern Chemistry, with one exception, are still with us. Neither does the volume include any account of the life-long labours of Berthelot, the senior Foreign Fellow of the Society, whose celebration of the fiftieth year of his scientific activity has so recently attracted the sympathetic attention of the whole civilised world. But the rising generation of scientific men may well be reminded in the words which M. Berthelot is reported to have spoken recently in the presence of the President of the French Republic at the Sorbonne, that it is not they who are making the science of the time, but their scientific ancestors. "If each of us adds something to the common domain in the field of science, of art, of morality, it is because a long series of generations have lived, worked, thought and suffered before us."

Experimentelle entomologische Studien vom physikalisch-chemischen Standpunktaus. Von Prof. P. Bachmetjew. Mit einem Vorwort von Prof. Dr. August Weismann in Freiburg i. Br. Erster Band. Temperaturverhältnisse bei Insekten. Pp. x + 160, mit 7 Figuren im Text. (Leipzig: Wilhelm Engelmann.) Price 4*s.* net.

HITHERTO the best-known researches into the temperature of insects have been those directed to the effects produced on the development or coloration of perfect insects reared from larvæ or pupæ which had been subjected to carefully graduated variations of high or low temperatures. There is, however, a very considerable literature, chiefly scattered in foreign periodicals, dealing with the temperature of insects from a much wider standpoint, especially as to their power of resistance to heat or cold. In the present work Prof. Bachmetjew, who commenced his researches in 1898, and who has already published some preliminary papers, has brought together and classified these scattered materials, adding to them the results of his own work.

The first section is devoted to the effects of temperature, moisture, movement, food, &c.; and the second to the extreme limits of heat or cold which insects are capable of resisting in their various stages. The bibliography at the end of the volume comprises, with additions, upwards of 200 references. The importance of this little volume of 160 pages is far greater than its unpretentious appearance would indicate, more especially as a very useful basis for further investigations and experiments. It is freely illustrated with diagrams and tables, and is too technical for a very detailed notice. The second volume, now in preparation, will be devoted to "Einfluss der äusseren Faktoren auf Insekten."

Flora of Guernsey and the Lesser Channel Islands. By Ernest David Marquand. Pp. viii + 501. (London: Dulau and Co., 1901.) Price 10*s.* 6*d.* net.

THE author of this work is to be congratulated on the way in which he has succeeded in his task of bringing up to date the state of our knowledge of a very interesting group of islands. The number of plants recorded in this volume for Guernsey and the lesser islands collectively is as follows:—

Flowering plants	828	species
Ferns and fern allies	29	,,
Mosses	156	,,
Hepaticæ	41	,,
Fungi	624	,,
Lichens	334	,,
Algæ	641	,,
Total	2653	species

The flowering plants and ferns are arranged and named in accordance with the last (eighth) edition of Babington's "Manual of British Botany." Each island is separately dealt with, and separate indexes are given for Guernsey, Alderney and Sark—the other five islands, viz. Herm, Jethou, Lihou, Crevichon and Burhou, not requiring one. For Burhou, indeed, less than a score flowering plants and ferns are recorded.

From the descriptive notes we learn that Guernsey is the most densely populated island on the face of the earth—a fact which the visitor, rambling through its country lanes, would find hard to realise. During the last twenty years the fruit-growing industry—owing largely to the extremely favourable climate—has advanced enormously. "At the present day there are certainly scores, if not hundreds, *of miles* of greenhouses in the island. . . . Every week-day during the spring and summer months large shiploads of vegetable produce leave Guernsey for the English markets, as many as 28,000 baskets and crates having been dispatched in a single day." Owing to draining operations and increased cultivation generally some of the rarer local plants will, before long, certainly disappear.

The first record for each plant is given, and interesting notes on its native names and former and present uses, &c. On p. 156 we find a blunder—one, however, repeated in every local flora, and indeed in many much more pretentious works which we have consulted—the plant there noted by Mr. Marquand is certainly not *Lycium barbarum*, but doubtless *L. chinense*. This last is a very different plant from the true *L. barbarum*, which is a thorny small-leaved desert plant—a native of North Africa—which is not anywhere naturalised in Britain or the British Islands. *L. chinense*, on the other hand, is a Chinese plant which readily naturalises itself.

G. N.

Water and Water Supplies. By J. C. Thresh, M.D., D.Sc. Medical Officer of Health to the Essex County Council. Third edition, revised and enlarged. Pp. xv + 527. (London: Redman, Limited, 1901.) Price 7*s.* 6*d.* net.

THIS work deals with the chemical composition and physical characters of water; the various sources from which it may be collected; the different ways in which it may be polluted and the effect on health of such pollution; the interpretation of the results of chemical analyses of water; the methods of purification and softening of water; the quantity required for domestic and other purposes; the protection of water supplies; the means of storage and distribution; and the law on water supplies.

Thus it will be seen that the subject is considered from every point of view of importance to those who are interested in providing a good water supply for domestic or trade purposes, and that the work appeals to a wide clientèle, to whom we have no hesitation in confidently recommending it.

For general accuracy, clear exposition and arrangement of subject-matter, and for evidence of a wide practical experience on the part of the writer, this work deserves to take a prominent place in public health literature. The book is well printed and tastefully bound.

LETTERS TO THE EDITOR.

Automatic Actions.

IN the interesting paper on "Reflex Action" by Dr. W. Benthall, published in your issue of September 5, he speaks of acquiring some feat of manual dexterity in which, with practice, the required muscular action becomes automatic. It seems to me that the same rule applies to many operations which are generally regarded as purely mental, such as in the use of the first four rules in arithmetic, in writing grammatically and spelling correctly, and in speaking any language. If you think, the action becomes laborious and in all cases the result is uncertain. In the case of spelling this seems to occur to every one, so that if you have to look up one word in a dictionary, which shows that you have begun to think about spelling, you have immediately to look up a number of others. Many people who are employed as clerks, &c., no doubt in adding a column of figures have their minds completely blank without their knowing it. In my own case, both at school and afterwards, I was very slow at this process and very uncertain of the results if the figures were numerous, as in a money column, but I found out, more than twenty years after I left school, that by thinking, not of the figures, but of nothing, the process was easy and rapid and the results correct. In speaking, say, French, if a person has to think of grammatical rules, the gender of nouns, &c., he can never speak fluently; to do so he must think of what he intends to convey and let the words take care of themselves.

Lower down Dr. Benthall quotes Dr. Lewis Robinson, who says: "The horse roamed in a wild state, over plains of more or less long grass and low bushes. When a horse is alarmed he throws up his head to get as wide a view as possible. The cow, on the other hand, keeps her head low, as if to peer under the boughs which covered the marshy grass of her jungle home." Cases of terror are only occasional occurrences amongst domesticated animals, but in the wild state the necessity of caution in the first movements on awakening from sleep, for fear of attack by some lurking foe, is evident. Now when a horse rises he gets on his fore feet and lifts his head high, whilst the cow rises on her hind legs first and keeps her head low. The horse being naturally a timid animal and rather unweildy in the process of getting on his legs has learned to sleep mostly standing and so be ready to move off at once, or kick as required; hence a stableman always speaks to a horse before approaching him from behind to make sure that he is awake and so unlikely to kick. WILL. A. DIXON.

Sydney, October 14.

Does Man use his Arms in Locomotion?

THE letter by Mr. Martin under this heading in your issue of November 28 raises the two interesting questions, (1) whether the swinging of the arms in walking and running serves any useful purpose as an aid to progression, and (2) whether this movement is a vestige, as Mr. Martin suggests, of the progression on all-fours of man's ancestors.

The following considerations may be of interest, though they are probably not put forward for the first time.

The movement of the legs in opposite directions in different planes involves a reaction, in the form of a couple, upon the trunk, tending to rotate it alternately in opposite directions about a vertical axis. That such a rotation does take place normally, when the arms are at rest, can be seen if the latter are folded upon the breast over a long light horizontal rod to serve as an indicator. This is very obvious when running. Now the swinging of the arms, each in unison with the leg of the other side, introduces an opposing couple which more or less completely balances, about a vertical axis, the reciprocating motion of the legs. The importance of the efficient "balancing" of the reciprocating and revolving parts of a railway locomotive, if steady and economical running is to be obtained, is well known.

That children and even adults, when compelled to crawl upon all-fours, naturally and unconsciously adopt the movements of the limbs common with four-legged animals is generally considered an indication that man has retained the instinct for this mode of progression, though the conditions for its adoption may seldom occur. It seems reasonable to suppose that the swinging of the arms in walking and running is a modification of this instinct for a modified purpose. C. O. BARTRUM.

17, Denning Road, Hampstead, N.W., November 30.

Folklore about Stonehenge.

I HAVE been waiting for more able pens than mine to corroborate Rev. Osmond Fisher's letter on the *culhes lapidum* in a recent issue of NATURE.

The same tradition about a loaf being placed on each stone to facilitate counting occurs in other places where sarsens have been objects of reverence in bygone ages. In April, 1895, Mr. Albany F. Major (hon. sec. Viking Club) and myself went on a visit to Kits Coity House above Aylesford, Kent. At the foot of Blue Bell Hill on the way to Kits Coity there are a number of sarsens in a field. On inquiring of a rustic as to their whereabouts, in directing us to them he informed us that a baker had made a bet he would count them and placed a loaf upon each stone in order to count them correctly. This is a slight variant of Mr. Fisher's statement about Stonehenge, but the underlying idea is the same. R. ASHINGTON BULLEN.

The Vicarage, Pyrford, Woking.

PRESERVATIVES AND COLOURING MATTERS IN FOOD.

THE report of the Departmental Committee upon this subject was issued last week and will be assuredly welcomed by all interested both in the public health and also in the trades concerned. The work of the Committee has been noticed at length in the lay Press and we think, speaking generally, has given satisfaction. Here we shall refer more particularly to the scientific aspects of the report. The Committee was practically a committee of experts, and we venture to think this precedent might be followed more frequently in the appointment of committees upon kindred subjects; trade interests are safe in the hands of impartial experts, and the exclusion of the trade from a committee of the kind saves time and, we think, also tends to the attainment of a most important desideratum, viz. unanimity.

For some time past there has been a large and apparently influential party of alarmists with regard to the use of preservatives. These have all been heard at length by the Committee which has just reported. Their evidence consisted for the most part of elaborate *a priori* argument, in support of which the most profound erudition was occasionally produced; but, as the report politely says, the opinion expressed was not always based directly upon fact. In fact, if an inquirer turns the 500 pages of the Blue-book over in search of unequivocal instances of injury to health from preservatives or, indeed, colouring matters in food he will be lucky if he finds a single one. There is no doubt some difficulty in fastening definite injury upon so subtle a cause, especially since heretofore the presence of preservatives has not even been declared. Yet, nevertheless, for the last two years practically the whole medical profession has been well alive to preservatives in food being a possible source of injury to health, and yet no definitely ascertained case, or practically none, has been forthcoming. Upon such data it is obvious that the prohibition of preservatives *en masse* was out of the question, and the recommendations of the Committee practically resolve themselves into the regulation and control rather than the prohibition of preservatives. There are, however, two exceptions to this; formaline or formic aldehyde is prohibited altogether, and all preservatives and colouring matters are prohibited in milk. The decision with regard to formic aldehyde might strike the casual observer in that nowhere in the report is it directly stated that this substance in the quantities necessary is injurious to health; a peculiar difficulty, however, arises with regard to it, viz., the practical impossibility of quantitative control. It is obvious that a substance of such

potency in unlimited quantity could not be sanctioned in food. The other exception, milk, is obviously also upon a different level; the fact that it forms the staple diet of invalids and children renders it especially important that it should be as pure as possible. It was, further, quite apparent from the evidence that the milk supply of London could be adequately maintained without preservatives, and, further, that these substances tended to mask uncleanly dairying. For the prohibition of colouring matter in milk there seems less reason. Annatto is admittedly harmless, and if the recommendations of the Milk Standardising Committee be adopted the fat standard will be uniform, and hence the colour will no longer be, at any rate in this regard, deceptive. Anything which improves the appearance of food, without it is harmful or done with direct intent to defraud in the physiological sense, that is to mask an actual nutritive deficiency, should be encouraged in that by pleasing the senses we can often help the digestion and, further, often save actual waste, as people will not eat what does not look nice.

This brings us to one point upon which, apparently, the Committee do not agree, viz., the use of copper sulphate for rendering preserved vegetables and fruits permanently green. Three members of the Committee recommend the prohibition of this practice, but Prof. Tunnicliffe is of the opinion that the amount of copper should be restricted to half a grain per pound and declared. The difference seems to be one of general principle *versus* specific fact. The Committee regard the addition of a substance to food which in certain quantities is undoubtedly poisonous to be undesirable in any quantity. It appears, however, that it is very questionable whether the copper compound actually present in the green peas is poisonous. Prof. Tunnicliffe's experiments show clearly that only a relatively small moiety of the copper is absorbed, or at any rate remains in the human system, when it is ingested in the form in which it occurs in preserved peas. These results are practically identical with those obtained by Brandl in the German Gesundheitsamt. People have taken peas greened with copper for almost half a century and no case of chronic or acute copper poisoning has so far been traced to this cause. We cannot agree that evidence of the injurious effect of copper would be difficult to obtain; copper chemically is one of the easiest substances to detect, and physiologically it produces well-marked and fairly characteristic symptoms. Had copper poisoning from coppered peas occurred, we think it would not have escaped detection. It is at any rate to be hoped that we shall not be consigned everlastingly to brown peas without further investigation.

Some surprise may perhaps be felt that salicylic acid was not prohibited, as this substance is undoubtedly possessed of active medicinal properties; it is, however, stringently controlled, only one grain per pound or per pint being allowed. This substance is a very active antiseptic, and is especially useful in jam making and temperance beverages. The complete sterilisation of jam is very apt to break up delicate fruits which it is certainly a pleasure to have whole. Many experiments have been made with salicylic acid, and in the quantities recommended by the Committee it seems quite harmless.

The appendices to the report will be full of interest to the expert; they comprise reports on very complete physiological experiments handed in by Prof. Tunnicliffe, being his own work in collaboration with Dr. Rosenheim and others, also reports of visits to Ireland and Denmark and many other invaluable reference data.

The work of the Committee must certainly be designated as thorough in the extreme, and their recommendations as eminently sensible. In particular we consider the suggestion as an excellent one that machinery should be provided either by the Local Government Board or by the formation of a separate Board of Reference for exercising control over the use of preservatives and colouring matters in food. It is sincerely to be hoped that legislation on the lines of the report will not be delayed; the necessity for it is urgent, as anyone can see who follows the conflicting decisions given in the law courts under the present Sale of Food and Drugs Act.

PRZEWALSKI'S HORSE AT WOBURN ABBEY.

A PERIOD of twenty years has elapsed since Poliakoff described an apparently new species of wild horse obtained by the late Colonel Przewalski in the deserts of Mongolia, under the name of *Equus przewalskii*. Although only a single example was then obtained, much interest attached to the discovery, as the animal appeared from the description to be in several respects intermediate between the domesticated horse and the wild asses, or, at any rate, the Asiatic representatives of the latter. For a long period nothing more was heard of the animal, and zoologists were uncertain whether they had to do with a real species or a hybrid, or possibly with one of the feral or wild representatives of the common horse. Within the last few years, however, other specimens—some alive—were received in Russia, and one skin was sent to the Paris Museum. Although no very detailed or well-illustrated description of them has hitherto appeared, these specimens appeared to demonstrate that Przewalski's horse was entitled to rank as a distinct species.

Still, without making a visit to Paris or Moscow, English naturalists had no opportunity of satisfying themselves by actual inspection as to the distinctness of this interesting animal, and the figures hitherto published left several important features in obscurity. The acquisition by the Duke of Bedford of a drove of twelve fine colts (imported by Mr. C. Hagenbeck, of Hamburg) has brought this unsatisfactory state of affairs to a close, and it is now possible to study the characters of the species (in an immature state) with some approach to exactness.

The colts at Woburn Abbey, which were foaled last spring or summer, are about the size of Shetland ponies; and, if we may judge by the absence of "legginess" in their build, do not seem likely to grow very large. In general appearance they are much more like ponys than donkeys, the ears being short and the tails haired to within a comparatively short distance of the root, although there appears to be a certain amount of individual variation in this respect. Eleven out of the twelve have, however, white muzzles, which communicate to the head a somewhat asinine appearance. All are in their winter (or ? first) coats, which are of a dun colour, with the front of the legs dark brown or black, the mane and tail being also black. The mane is at present upright, but exhibits a slight tendency to fall over, which may increase with age; and there does not seem, at least in most cases, to be a distinct forelock. Most of the colts show no dorsal stripe, although in one or two there is a short one on the rump. There is no trace of a shoulder-stripe, or of dark barrings on the legs. Both fore and hind legs have callosities. So far as I can recollect, the underparts are lighter than the back. In young animals the true form of the hoofs is not fully developed, but I think the hoofs of these colts are of the relatively large size characteristic of the horse and the Asiatic wild ass.

The Woburn colts render it quite certain that *Equus przewalskii* is a true species and not a hybrid. It is equally clear that it is perfectly distinct from the kiang and all other races of the Asiatic wild ass.

The only other animal with which Przewalski's horse could be identical is the tarpan, or wild (or feral) horse of the Kirghiz steppe, which, as I am informed, is now extinct. Tarpan are, however, described by Pallas as

having a distinct dorsal stripe on the otherwise dun back, and a well-developed forelock, while the muzzle, with the exception of the nose[1] (which is whitish), is said to be black, and the tail, which appears to be haired to the root, is rather short and bushy in winter. Moreover, the colour of the tail and mane is said to be reddish-brown. Nothing is stated with regard to the front of the legs being black.

So far as can be determined from this description, the tarpan appears identical with *Equus caballus* (of which it is probably the ancestral form), which is certainly not the case with *E. przewalskii.*

But another important point arises in connection with the animal under consideration. Naturalists commonly divide the existing species of Equus into two groups, the one containing only the horse, and the other the asses and zebras. Przewalski's horse will, however, clearly find a place in the former group, and as this animal approximates in some respects to the kiang, which differs from the African wild asses by its shorter ears, larger hoofs (especially the front pair) and absence of a shoulder-stripe and bars on the legs, I am inclined to think that the horse, Przewalski's horse, and the kiang (Asiatic wild ass) form one natural group, and the African wild ass, quagga and zebras a second. This arrangement will harmonise with distribution much better than the old one.

Taking the tarpan as the wild representative of the horse, it will be noticed that all three members of the first group agree in the general absence of the shoulder-stripe and of dark markings on the legs. And the question then arises, how is it that certain domesticated horses (especially dun-coloured ponies in the Punjab) show both these markings? Can it be owing to a cross with the African ass, or is it due to reversion to the common ancestor of the equine genus? R. L.

TYCHO BRAHE'S OBSERVATORY.

IT was mentioned in a recent article on the tercentenary of Tycho Brahe's death (p. 6) that an account of excavations made in the island of Hveen has been published by Prof. Charlier, of Lund.[2] As Tycho's observatory has thus again attracted attention, it may not be out of place to give a short description of it as it was three hundred years ago, and of the very few remains of it now brought to light.

Tycho's magnificent buildings were destroyed less than twenty-two years after his death. In 1623 a mason was paid for 60,000 bricks "which he had pulled down and renovated from the old castle," and they were used to build a new dwelling-house at a little distance, which in its turn has disappeared within the last hundred years. Apparently the peasants of the island helped themselves to bricks and stones as much as they liked, as part of the foundation-stone (laid by Tycho's friend the French envoy, Charles de Danzay) was recently discovered in the wall of an outhouse of a farm on the east coast of the island, still showing part of the Latin inscription and the date 1576 August 8. When Picard was sent over by the Paris Academy, in 1671, to determine the geographical position of Uraniborg, only the foundations of the house and the greater part of the ramparts surrounding it were still intact, while on the site of the observatory only a slight hollow in the ground was noticeable. Picard did not trouble himself about making excavations, and apparently everything was left undisturbed until 1823, when the clergyman of the island, Ekdahl, made careful excavations. At Uraniborg he found the deep well which was under Tycho's kitchen and still supplies the neighbourhood with excellent water, while parts of the foundation-walls and some slight remains of the laboratory (in the basement of the house) were also unearthed. These must have been covered over again, as nothing was visible on this spot until the present year, when the same trifling ruins of Tycho's beautiful residence were again laid bare; but as nothing of any scientific interest was found, we may at once pass to the underground observatory, of which much more distinct traces still remain.

Uraniborg, the stately residence of Tycho Brahe, was finished in 1580 and contained four observing rooms, two at the north and two at the south end of the building. But already a year or two later a large meridian quadrant was erected in one of the sitting-rooms, and very soon, as the work increased, it was found that even with this addition to the equipment more instruments were wanted. In 1584 an observatory was therefore built on a low hill about a hundred feet south of the south corner of the enclosure of Uraniborg and slightly to the east. This observatory, of which we here give a view from the west and a plan,[1] was called Stellæburgum (Danish, Stjerneborg); in it the instruments were placed in three subterranean rooms (C, G and F on the plan), of which only the roofs rose above the ground, so that they were well protected from the wind. The entrance was to the north, and in the centre was a study, lighted by four small windows just above the ground, and which could be heated by a stove in a recess (at P), while off it there was an alcove with a bed where Tycho could rest during cloudy intervals. In 1585 two other rooms for instruments (D and E) were added, but the floors of these were almost on the level of the ground, probably because he had found it inconvenient not to be able to observe stars near the horizon from the three underground rooms. The whole was surrounded by a low wooden paling, forming a square with sides 57 feet long, with semicircular bends at the middle of each side of 20 feet diameter, and stone piers were placed inside the

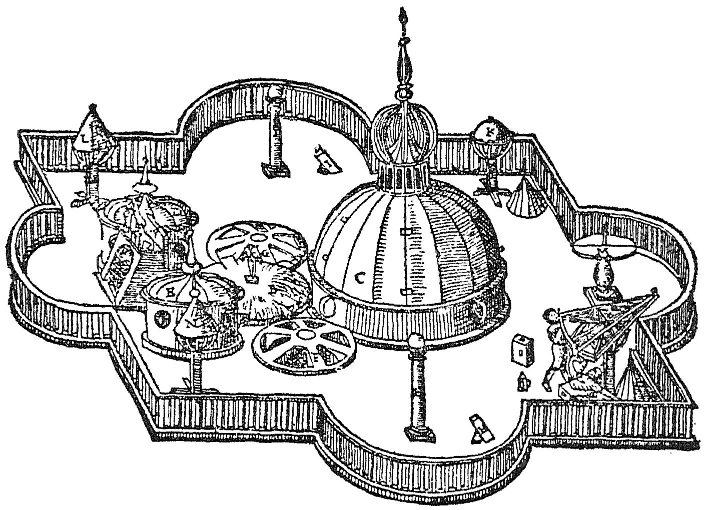

FIG. 1.—Stjerneborg Observatory, seen from the west.

[1] The expression "nose" is a little ambiguous, but the figures do not show a white muzzle like that of *E. przewalskii.*

[2] "Utgräfningarna af Tycho Brahe's observatorier på ön Hven sommaren 1901." Beskrifna af C. V. L. Charlier. 20 pp., 4to, with 3 plates. (Lund, 1901.)

[1] Taken from the writer's book, "Tycho Brahe," by permission of Messrs. A. and C. Black.

enclosure, on which portable instruments could be used when necessary.

In the centre of each crypt was a large instrument, the floor rising gradually by circular stone steps (shown on the plan) up to the walls. The floor of the crypt G was, however, flat; in it was placed a sextant of $5\frac{1}{2}$ feet radius for measuring angular distances in any plane. In the southern crypt (C) there was a large equatorial instrument, consisting of a declination circle of $9\frac{1}{2}$ feet diameter, revolving round a diameter parallel to the earth's axis, and having a semicircle of 12 feet diameter, supported on stone piers and representing the northern half of the equator. In the crypt F stood a quadrant of 7 feet radius, enclosed in a square and with an azimuth circle on the wall, in D another quadrant somewhat smaller and in E a zodiacal armilla like those used by the ancients. Of these instruments those in C and F were the most important, and an immense deal of valuable work was done with them.

Of this observatory and of the instruments in it very full and well-illustrated descriptions were published by

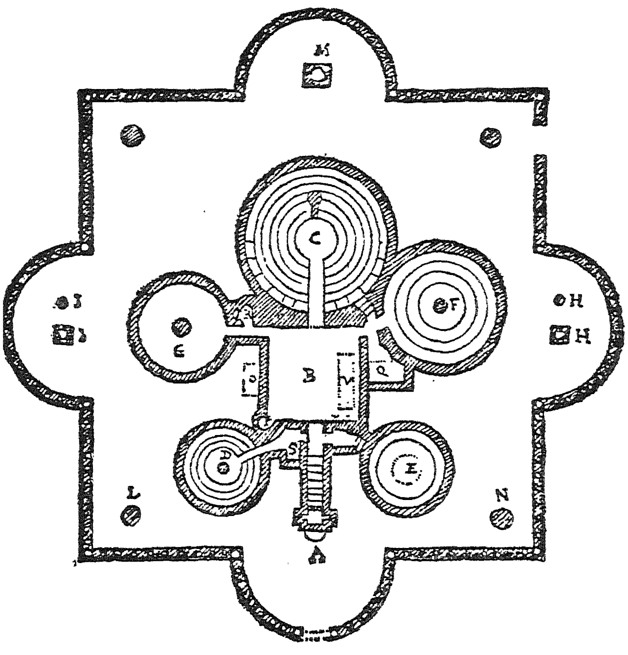

FIG. 2.—Plan of Stjerneborg:—A, entrance; B, study; C, crypt with largest armillæ; D, crypt with quadrant: E, crypt with zodiacal armillæ; F, crypt with largest quadrant; G, crypt with sextant; H, I, stone piers for portable armillæ; K, L, N, T stands for sextants; M, stone table; O, Tycho's bed; P, stove; V, table: Q, bedroom for assistants; S, unfinished underground passage towards Uraniborg.

Tycho. When he left Denmark he took all his instruments with him except the four largest, two of which were those in the crypts C and F, and the large equatorial was actually used by an assistant to observe the partial eclipse of the sun of February 25 (March 7), 1598.[1] They were, however, subsequently dismounted and sent to Bohemia, where every single instrument from Hveen was destroyed during the thirty years' war, except Tycho's large star-globe, which found its way back to Denmark only to perish in a great fire in 1728.

When Ekdahl, as already mentioned, examined the site of Stjerneborg in 1823–24, he found without difficulty the floors of the central study and of all the crypts more or less well preserved, one of them (F) being almost perfect, with the four circular steps and the short stone pillar in the middle on which the quadrant had been fixed. In the course of years everything became again covered with earth and grass except the crypt F, which was always visible, though generally more or less full of water. It furnished a valuable clue to the unit of linear measure employed by Tycho, as d'Arrest, in 1868, found the diameter of the crypt to be $11\frac{1}{3}$ Paris feet, which must be equal to the diameter of the azimuth circle of the quadrant which Tycho states to have been nine cubits. This gives one cubit = 16·1 English inches = 40·9 centimetres. Tycho, however, also makes use of feet, and d'Arrest found to his surprise, on measuring the length of the ramparts round Uraniborg, that the whole place was much smaller than the figures given by Tycho had led him to expect, the enclosure being only 233 French feet square instead of 300. The discrepancy was, however, easily cleared up, as Picard had carefully measured the great star globe in 1671, which gave one Tychonic foot = 0·815 English = 24·9 centimetres. These figures are of importance, as it is of interest to know the exact dimensions of the instruments, by means of which so great a revolution in practical astronomy was carried out. For instance, the radius of the great quadrant (in F) was five cubits long; one minute of arc was, therefore, 0·6 millimetre in length, and as Tycho says that he could by his transversal divisions distinguish 10″, this means that he could read off the arc to a tenth of a millimetre. In reality the accuracy attained was hardly as great, the probable error of one measure of altitude being certainly more than half a minute. But even this was a wonderful advance on what had been possible before Tycho's time, when errors of three or four minutes were unavoidable.

During the past year the site of the observatory has again been thoroughly excavated under the supervision of the Swedish inspector of antiquities and Prof. Charlier, of Lund. From the account published by the latter it appears that the tiled floor of the central study is almost perfectly preserved; it is 4 metres long (from north to south) by $3\frac{1}{2}$ metres broad. The floor of the alcove where Tycho's bed stood is also visible, the dimensions being only 185 by 125 cm. As it seems to have been completely underground, this tiny and grave-like bedroom can hardly have been a healthy place of rest, and it is to be hoped that the energetic observer did not use it very often. The floor of the study was found to be two metres below the ground. As Prof. Charlier's account is in Swedish, it may not be useless to give here a summary of the results of his examination of the five crypts. Of D, G and C the floors are left, all on the same level as the floor of B, and in D also the short pillar to which the lower end of the vertical axis of the quadrant was attached. The polished stone floor of E was 125 cm. above that of the study B and the steps leading up to it from the little vestibule north of the study are still intact. But the crypt F is almost in perfect preservation, with its four steps, the floor being 122 cm. below that of the study (or 10 feet below the ground), the inner diameter of the lowest step being 88 cm. and the outer diameter of the top step 345 cm. The top step was exactly on a level with the floor of the study. As the diameter of the top step was of importance for fixing the length of Tycho's cubit, it was measured again by a second observer, who found 354 cm. The mean of the two measures gives 1 cubit = 38·8 cm., agreeing sufficiently well with the 40·9 found by d'Arrest. Prof. Charlier found the value of a Tychonic foot from measures of the length of the foundation-wall of Uraniborg equal to 23·8 cm.; but as Tycho only says that the side of the square was "circiter pedes 60," this result can hardly be as accurate as that deduced from Picard's measure of the star-globe, as it seems likely that the latter was exactly 6 Tychonic feet in diameter, which Picard found equal to $55\frac{1}{12}$ French inches.

[1] See *Monthly Notices* R.A.S., vol. liv. p. 439.

The account of the recent excavations of Tycho's observatory thus forms a valuable supplement to the description published by Tycho himself. The idea of seeking shelter from the wind, by erecting his large instruments a couple of feet below the level of the ground, was a good one, and on the small island the force of the wind was doubtless not a negligeable quantity, particularly as the observatory was situated almost at the highest point of the island, about 160 feet above the sea, which is visible in all directions except in the south-east. Picard remarked that except where some hills in Scania rise to an altitude of 11′, he had often seen the stars down to the very horizon, which he considered very surprising, as this was never possible at the Paris Observatory, although the latter was about 120 feet higher than the level of Tycho's observatory. But the example thus set by Tycho was not followed; for more than a hundred years the object seemed generally to be to get as near to the stars as possible by placing observatories on the top of towers and high buildings—and in the midst of crowded cities. The nineteenth century has reverted to Tycho Brahe's ideas by building observatories at some distance from cities and with the instruments at very moderate heights above the ground. Another idea of Tycho's, which was not adopted for several centuries, was to have a large staff of assistants, among whom the work of the observatory was divided. He had cherished the hope for many years that the institution founded by him would be made a permanent one and not come to an end with his own life. Unfortunately he did not succeed in getting this settled in the lifetime of his benefactor, King Frederic II., and when he finally found that not only was it hopeless to expect a permanent endowment, but that even some of the valuable grants he had enjoyed for years were taken from him, he resolved to try if some other monarch would carry out his favourite idea and found a public observatory on a large scale. But Tycho had been very many years in his grave before this was done anywhere.

J. L. E. DREYER.

TECHNICAL SCHOOLS FOR RURAL DISTRICTS.

ENCOURAGED by the success which has attended the work of her sister, the Countess of Warwick, at Bigods, near Dunmow, in Essex, the Duchess of Sutherland has boldly entered upon a scheme for providing a technical school in a still more remote rural district, viz. near Golspie, on their Dunrobin estate in Sutherlandshire. No provision for secondary and technical education in the Scotch Highlands at present exists, and the proposed school must meet a long-felt want. The draft scheme which has been drawn up by the Duchess with the cooperation of Prof. Meldola provides for the education of fifty pupils in the principles of those sciences which bear in any way upon the local industries, including agriculture. The pupils will be taken from the elementary schools and admitted only when fully qualified to take advantage of the secondary training offered by the Sutherland school. In view of the excellent character of the elementary teaching in the Scotch schools, there should be no difficulty in finding a constant supply of promising pupils, the more especially as the new school is intended for board and residence and caters for the four counties of Sutherland, Ross, Cromarty and Caithness. Like Bigods, the Sutherland technical school is to be mixed and the curriculum adapted to the requirements of boys and girls. As stated in the scheme:—

"It is impossible that education in the Highlands should continue on the present lines. There is practically no technical training whatever. The old form of 'classical' education is still persisted in, and often a whole school suffers for the sake of three or four clever pupils who win the bursaries which send them to the University, from whence they issue as clerks, doctors or ministers as the case may be. The others are left to drift into idleness or to go away south to add to the population of our already over-crowded cities. The overcrowding of the fisher class is undisputed, and the dearth of skilled masons, carpenters and artisans, or competent hand-workers in the north, apart from the homespun tweed industry, is remarkable. There have been many peripatetic technical classes carried on under the County Councils and School Boards in the north, but this is the first technical school of the kind that has been started in the Highlands. It should be the pioneer of much educational reform, and it is started with a great belief in its ultimate possibilities."

The scheme has been considered by many educationists and has been approved of by Lord Balfour of Burleigh, Mr. Struthers, of the Scotch Board of Education, Sir Swire Smith, Mr. James Baker, Prof. Magnus Maclean and others. Practical appreciation of her Grace's efforts in the cause of education has also been shown by the substantial support which the scheme has already received. The Duke of Sutherland has given the site for the building and land for the agricultural work close to Golspie, besides 5000*l.* towards the building and equipment fund. Mr. Andrew Carnegie contributes 5000*l.* to the same fund and Mrs. Carnegie two bursaries of 30*l.* each annually. The Duke and Duchess of Sutherland, the Dukes of Westminster and Portland, and Mr. James Coates, of Paisley, also contribute annual bursaries. The work thus commences under very good auspices and is worthy of the most cordial support by all who are interested in the welfare of Scotland. At the present time, when "official" educators are, as was said recently, whistling for the wind of popular opinion, the country may well be proud of the splendid examples set by the Countess of Warwick in Essex and by her sister in the Highlands of Scotland. As pioneers in the introduction of scientific education into rural districts the names of these ladies will be written large in the annals of our educational development.

A PERIODICAL FOR STATISTICAL BIOLOGISTS.[1]

THE receipt of the first part of the new periodical, *Biometrika*, calls for more than mere formal acknowledgment. The methods of investigating biological problems statistically may be looked upon as having their origin in this country, and the names of the editorial staff are those of the pioneers in this modern departure—Francis Galton, and Profs. W. F. R. Weldon and Karl Pearson, associated with Prof. C. B. Davenport, of the University of Chicago. The part received is prefaced by an editorial article setting forth the scope and defining the spirit of the publication and an article on biometry from the pen of Mr. Galton. An admirable figure of the Darwin statue in the University Museum at Oxford, reproduced from a photograph by Mrs. E. B. Poulton, forms an appropriate frontispiece, the motto "*Ignoramus, in hoc signo laboremus*," being printed below the illustration. The papers contributed to this first part are seven in number, including those already mentioned. Prof. Dr. F. Ludwig writes (in German) on problems and materials for variation statistics; Mr. A. O. Powys con-

[1] *Biometrika.* A Journal for the Statistical Study of Biological Problems. (Cambridge: University Press. New York: The Macmillan Company.) Price 10*s.*

tributes data for the problem of evolution in man, anthropometric data from Australia; Miss Beeton and Prof. Pearson furnish a paper on the inheritance of the duration of life and the intensity of natural selection in man; Mr. E. T. Browne writes on variation in *Aurelia aurita*, and Prof. Weldon on a first study of natural selection in *Clausilia laminata*.

This first list of contributions augurs well for the future of an undertaking which deserves support from all workers in science who are interested in the theory of organic evolution in its broadest applications. The points of contact between mathematicians and biologists have hitherto been but few, and the time is yet remote when we may look for the advent of a skilled mathematician who shall also be an expert biologist, or *vice versâ*. But although the modern biologist may be unable to follow the mathematical processes of the new method, he will assuredly be impressed with the importance of the results, and such a work as that which has now been launched will serve as a common meeting ground for both classes of workers. The recognised methods of studying living organisms from the points of view of systemy and taxonomy, embryology, histology and anatomy, bionomics and distribution have all contributed to the sum total of that great division of natural knowledge which is known by the comprehensive title of biology. Side by side with these we must now place the newer statistical methods inaugurated with such marked success by Galton. This latest claimant to recognition as a legitimate weapon of scientific attack may be looked at with suspicion by those who are accustomed only to the older methods. We may remind our readers, however, that the value of measurement and statistical treatment was fully realised by Darwin, as made clear in one of the editorial articles in the present part of *Biometrika*. We may point out also that Wallace in his "Darwinism" (1889) fully recognised the value of such methods, and made considerable use of the measurements of lizards by Milne-Edwards and of birds by Mr. J. A. Allen for his discussion of the question of individual variability as furnishing the material for the operation of natural selection. Such data were imperfect compared with the modern requirements of statistical methods, but so far as they went they have been of service to the cause of Darwinian evolution, and this fact, again, tells strongly in justification of the appearance of a new periodical devoted entirely to this phase of biology.

There is no real antagonism—as some men of science have supposed to exist—between the older methods and the latest statistical methods. They are, or should be, on the contrary, mutually helpful. If by the measurement of large numbers of individuals and the mathematical treatment of such data the trend of evolution in any species can be detected, here at once is a suggestion for the observing naturalist to work upon—to endeavour to find out the nature and cause of the survival in a certain direction; in other words, to hunt down the selecting agent. Where ordinary observation has in so many cases failed, the newer methods appear to open out endless possibilities of attacking such problems. The student of bionomics will, as statistical data and their deductions accumulate, have definite information given as to what is going on in particular species, and it will be for him to approach the study of such species armed with specific questions awaiting answer in the field or laboratory. We venture to think that, far from any antagonism existing between the older and newer methods, the introduction of statistics in the Galtonian sense cannot but give a great impetus to observational work. It may be added that the periodical is really cosmopolitan, and the editors invite contributions in German, French or Italian, as well as in English. We cordially wish the new journal the success which it merits.

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

THE anniversary meeting of the Royal Society was held as usual on St. Andrew's Day, November 30, when the annual report of the Council to the Fellows was presented. Among the subjects mentioned in this report is the proposal to establish a British Academy, which was discussed at a special meeting of the Society held in May last.

Reference is made by the Council to the subject of the tenure of office of the secretaries, which was recently raised again. A memorial "praying the President and Council to take into immediate consideration the advisability of limiting the tenure of office of any future treasurer or secretary," and also a memorial expressing the decided convictions of the memorialists that the change advocated by the preceding memorial would not be in the interests of the Society, were taken into consideration at the meeting of the Council on November 7. It was proposed, as a resolution, "That in the opinion of this Council it is desirable that the secretaries should not be so re-elected as to hold office for a period exceeding ten consecutive years, this resolution not to apply to the present holders of office," and, after considerable discussion and the consideration of various amendments, the resolution was carried.

As already announced, in consequence of his appointment as Principal of the University of London, Prof. Rücker has resigned his office as secretary, and is now succeeded by the distinguished mathematician and physicist, Dr. Joseph Larmor.

The address of the president referred to the scientific work of the Fellows and Foreign Members deceased since the former annual meeting, and a few investigations commenced or carried on in the course of the year. The work of this year's medallists was described as follows:—

COPLEY MEDAL.

Prof. J. Willard Gibbs, Foreign Member, R.S.

The Copley Medal is awarded to Prof. J. Willard Gibbs, a Foreign Member of this Society, for his contributions to mathematical physics.

Although Horstmann had demonstrated, between 1869 and 1873, the applicability of the mechanical theory of heat to the elucidation of the phenomena attending dissociation, J. Willard Gibbs was the first to apply the second law of thermodynamics to the exhaustive discussion of the relations between chemical, electrical and thermal energy and capacity for external work. His great contribution to this subject appeared in the *Transactions* of the Connecticut Academy in two parts, the first in 1875 and the second in 1878. In this paper, which opens with a discussion of the criteria of equilibrium and of stability as applying to a material system, the conditions of equilibrium prevailing in both homogeneous and heterogeneous systems of gaseous, liquid and solid materials are considered in a highly generalised form; and it is shown by Gibbs that Deville and Troost's experimental values of the density of nitrogen peroxide at different temperatures, and Playfair and Wanklyn's results obtained with mixtures of nitrogen peroxide and nitrogen, can be interpreted quantitatively with the aid of his fundamental gas equation.

The most important result of Gibbs's work, from a chemical standpoint, is the so-called "phase rule," the law which governs the general case of complete heterogeneous equilibrium. This law, which was developed theoretically, states that a system in complete heterogeneous equilibrium must be composed of at least n different molecular components if it consists of $n+1$ different phases.

The application of the phase rule has been repeatedly verified experimentally under a great variety of aspects. During the last few years the recognition of the law has led, amongst other important results, to a complete systematisation of our knowledge concerning dissolution of solid substances, the distribution of a solute between two immiscible solvents, and to the formation of double salts and of racemic, pseudo-racemic, non-racemic

and externally compensated substances. The phase rule has also been applied with complete success by van 't Hoff to the elucidation of the formation of oceanic salt deposits. In fact, Willard Gibbs's generalisation is applicable to all cases of reversible chemical interchange, and consequently to chemical change generally.

ROYAL MEDAL.

Prof. William Edward Ayrton, F.R.S.

A Royal Medal is given to Prof. William Edward Ayrton, F.R.S., for his contributions to electrical science.

The services rendered by Prof. Ayrton to science during the last twenty-seven years may be roughly grouped under two heads. He has carried out a large number of researches in pure physics, and he has taken a very prominent part in the development of the application of electricity to industry, which has been so remarkable a feature of the closing years of the nineteenth century. It is not here necessary to refer particularly to his researches, invention and inspiration under the second head. At all times he has been doing service under both heads. From 1873 to 1878, in Japan; from 1879 to 1884, at Finsbury; and from 1884 to the present time, at the Central College, Kensington, he has acted as professor of physics; he has arranged large laboratories, and through his own example in research he has inspired many students, who are now carrying out investigations of their own.

A large number of papers contributed, sometimes alone and sometimes in partnership with others, to the Royal Society *Proceedings* and *Transactions* and other scientific publications, while belonging to the second group above mentioned, have greatly assisted in pure physics.

It is not out of place to quote a published remark of the late Prof. Clerk Maxwell in reference to the work of Prof. Ayrton and a colleague in Japan, that they had moved the centre of gravity of electrical science greatly eastward.

ROYAL MEDAL.

Dr. William Thomas Blanford, F.R.S.

The other Royal Medal is conferred upon Dr. William Thomas Blanford, F.R.S., for his work in connection with the "Geographical Distribution of Animals."

Dr. W. T. Blanford received his scientific education at the Royal School of Mines, and, after special instruction in the methods of geological surveying under Prof. (afterwards Sir Andrew) Ramsay on the English Geological Survey, proceeded in 1855 to take up a post on the Geological Survey of India.

Between the years 1855 and 1868, when he was engaged in surveying different parts of India and Burma, he published a number of valuable papers on Indian geology, and upon malacology and other branches of natural history, based on observations made during his travels as a geological surveyor.

In 1868 he was appointed to accompany the expeditionary force under Lord Napier to Abyssinia in the capacity of naturalist, and his observations on the geology and fauna of the country are published in a number of communications to scientific journals and in his work, "Observations on the Geology and Zoology of Abyssinia," published in 1870.

Between 1868 and 1872, Dr. Blanford returned to his work on the Geological Survey of India, and as the result of his labours in Sind, Cutch, the Deccan and other parts of the country, a number of memoirs dealing with geology, malacology and ornithology were published by him. In 1872 he was selected to act as naturalist to the Persian Boundary Commission and the results of his observations appeared in a work, "Eastern Persia, vol. ii., Zoology and Geology," which was published in 1876.

Returning to India, he not only carried on the usual survey work, but, in conjunction with Mr. H. B. Medlicott, prepared the important "Manual of the Geology of India," 3 vols., 1879. In this work a most valuable summary of the geological observations which had been made upon all parts of the Indian Empire is given, with a discussion of the age and relationships of the formations of that vast district.

Since his return from India, in 1882, Dr. Blanford has been continuously engaged in zoological and geological researches. His memoirs on the rocks of India and Australia which exhibit glacial conditions, and on kindred subjects, have been most valuable contributions to geological science. Equally important have been the two addresses on "Geological Nomenclature" and "The Permanence or otherwise of Ocean Basins," which he delivered in his capacity of president of the Geological Society in 1889 and 1890. In the last-mentioned address he has laid down principles and established conclusions which have given a new aspect to the study of the geographical distribution of animals.

"The Fauna of India," published under the authority of the Secretary of State for India in Council (8 vols., concluded in 1898), was edited by Dr. Blanford, who has contributed three volumes on birds and mammals. This work has been most favourably received by the scientific public and is looked upon as the standard authority of Indian vertebrates. His contributions to this work constitute his special claim to a Royal Medal.

Dr. Blanford is one of the few men who are regarded as an authority on geology, palæontology and zoology, to each of which branches of science he has largely contributed.

DAVY MEDAL.

Prof. George Downing Liveing, F.R.S.

The Davy Medal is awarded to Prof. George Downing Liveing, F.R.S., for his contributions to spectroscopy.

Prof. Liveing's papers on spectroscopic subjects have been mainly published during the last quarter of a century in conjunction with Prof. Dewar, and have appeared for the most part in the *Proceedings* of the Royal Society. They make up a record of patient, accurate, conscientious labour, and, taken together, constitute one of the most valuable contributions to this department of chemical physics yet made by British workers.

SYLVESTER MEDAL.

Prof. Henri Poincaré, Foreign Member, R.S.

The Sylvester Medal, given this year for the first time, is awarded to Prof. Henri Poincaré, a Foreign Member of this Society, for his many and important contributions to mathematical science.

Prof. Henri Poincaré's mathematical writings display very great originality, independence of thought and far-sightedness. The number of the memoirs and works which he has published is extraordinary, and the wide range of subjects in pure mathematics and its applications to astronomy and physics which they cover is equally remarkable. The bond of unity which connects his investigations is that nearly all have a more or less intimate connection with the study of differential equations. He has dealt with the theories of linear differential equations, of ordinary non-linear differential equations and of partial differential equations, with striking results in each theory; and each is associated with a department of his other important researches.

In the theory of linear differential equations, Fuchs had called attention to the substitutions by which different particular integrals are interchanged at the critical points. The substitutions form a group, and (at any rate when the equation is of the second order) there exist automorphic functions which are unchanged by the operations of the group. M. Poincaré has constructed these functions and shown how by means of them a complete integration of the linear differential equation can be effected (*Acta Mathematica*, t. iv.). He has devoted five classical memoirs (*Acta Mathematica*, i., iii., iv., v.) to a profound study of the automorphic functions and Fuchsian and Kleinian groups. Closely related to the same study are his delicate researches as to the topology of loci in space of n dimensions, and a number of contributions to the theory of algebraic functions.

In the theory of ordinary differential equations (not linear) he has introduced a new method of dealing with the question of the existence of a solution, and has shown how various methods of approximating to a solution may be utilised for solving the problem which gives rise to the differential equation. This lies at the root of his investigations in connection with the equations of dynamics and the special problem of gravitational astronomy —that of n bodies. He has shown that G. W. Hill's periodic solution of the problem of three bodies is one of an infinite system. M. Poincaré has also discussed from the point of view of modern analysis the methods of solution in periodic series which are associated with the name of Laplace and with the problem of the stability of the solar system, and has been led to give the first complete theory of series of the kind now called "asymptotic" and to point out their uses in analysis.

Mathematical physics requires the investigation of certain

partial differential equations, and the problem arises to develop a formula from which the solution, subject to boundary conditions, can be calculated. The problem can in any case be reduced to the discovery of what is now called a Green's function. To Poincaré is due perhaps the most feasible means yet devised for arriving at these functions. A general analytical theory has also been given by him of a somewhat different problem, required in theories of vibration and electrical oscillation. The diffraction of light has also been discussed by him in an elaborate memoir.

He has besides enriched pure mathematics with researches in the theory of numbers and on double integrals. In applied mathematics he has obtained remarkable results with regard to the figures which can be assumed by rotating fluid. To dynamical astronomy he has contributed, not only memoirs, but a monumental work in three volumes—"Les Méthodes Nouvelles de la Mécanique Céleste."

Finally, allusion may be made to the services which M. Poincaré has rendered to a number of branches of mathematical physics, by critical presentation of the work of others in published courses of lectures.

The officers and Council elected for the ensuing year were the Fellows whose names have already been given (p. 34), with two others to supersede two Fellows who found themselves unable to serve (p. 85).

On the evening of Saturday, the Fellows and their friends dined together in the Whitehall Rooms, when, to quote the *Times* report, "no Cabinet Minister and only one ex-Minister—Mr. John Morley—was present. Thus the calm discourse of the men of research was undisturbed by even the suggestion of political strife." It might also have been added that thus do Ministers of State manifest their indifference to associations having no political significance.

NOTES.

WE regret to announce the death of Sir William MacCormac, the distinguished president of the Royal College of Surgeons.

PROF. YVES DELAGE has been elected a member of the section of anatomy and zoology of the Paris Academy of Sciences in succession to the late Prof. Lacaze-Duthiers. Prof. Gouy, professor of physics in the University of Lyons, has been elected a correspondant of the Academy in succession to the late Prof. Raoult.

IN response to appeals made by the Dover Chamber of Commerce to the Trinity House to place wireless telegraphy installations on the lightships in this part of the English Channel, an intimation has been received by the Chamber that the matter is under consideration by a special inter-departmental committee.

THE National Antarctic Exploration ship *Discovery* arrived at Lyttelton on Nov. 23. The ship has been dry-docked for caulking, having sprung a leak, though not a serious one.

MR. JONATHAN HUTCHINSON, F.R.S., is about to proceed to South Africa with the view to study the cause of leprosy. He will proceed to Robben Island, and will probably go on to Natal and Basutoland. His object is especially to obtain facts as to the use of dried and badly salted fish. Leprosy is a comparatively new disease in Cape Colony, and quite so in Natal and Basutoland. Thus these districts offer exceptional opportunities for ascertaining its cause.

THE Berlin correspondent of the *Times* reports that the German Imperial Estimates include the sum of 150,000 marks (7500*l.*) to be devoted to the prevention of tuberculosis and to the investigation of that disease. The sum will be largely applied to the promotion of research with the object of settling the question of the identity of tuberculosis in human beings and in animals. For the promotion of markets for agricultural produce and for the support of scientific, technical and kindred undertakings in the interest of agriculture a sum of 90,000 marks will be demanded, as against 50,000 marks last year.

EX-GOVERNOR EYRE, who died on Saturday at the age of eighty-six, was less known perhaps for his geographical work than for his action in connection with the disturbances in Jamaica thirty-six years ago. Yet he was an intrepid explorer, and in 1843 he received the Founder's Medal of the Royal Geographical Society for his explorations in Australia. He crossed the Australian continent overland from Sydney in the east to Swan River in the west, and investigated the then unknown shore of the Great Australian Bight between King George's Sound in Western Australia and Port Lincoln in South Australia. In 1845 he published the results of his explorations in a work entitled "Discoveries in Central Australia."

A SPECIAL expedition, under Dr. Charles Balfour Stewart, has just been sent by the Liverpool School of Tropical Medicine to the Gold Coast and to the gold-mining districts of that colony, to conduct a series of operations there with a view to improve the conditions of health and sanitation. Dr. Stewart was to have sailed for Cape Coast Castle on November 16, but his departure had to be delayed as the municipal authorities of Liverpool requisitioned his services to deal with an outbreak of plague in the city. The lines on which Dr. Balfour Stewart will proceed will be similar, so far as possible, to those now being followed by the Sierra Leone expedition of the Liverpool School under Dr. Logan Taylor.

THE death is announced of Mr. Samuel Rowles Pattison, who for some years was a member of Council of the Geological Society and its honorary legal adviser. In early life he resided at Launceston, where he made a collection of fossils from the limestone of Petherwin, and assisted by his local knowledge both De la Beche and John Phillips. He contributed papers on local geology to the *Transactions* of the Royal Geological Society of Cornwall and the Royal Institution of Cornwall from 1840 to 1860; and in the *Quarterly Journal* of the Geological Society of London he recorded the occurrence of auriferous quartz-rock in north Cornwall. In 1858 he published a work entitled "The Earth and the Word; or Geology for Bible Students." Mr. Pattison, who had attained the ripe age of ninety-two, died on November 27.

THE results of an analysis of the returns relating to the outbreak of small-pox in London are given in an article in Saturday's *Times*. There have been 349 completed cases, that is, cases which have ended in death or recovery, since May last. Of these 349 patients 181 were males and 168 females. The number of deaths was 116, and the rate of mortality was three times as great among the unvaccinated as among the vaccinated. The following points brought out by the classification of the cases are instructive:—(1) All the cases under five were unvaccinated, and out of 23 there were 19 deaths; (2) all the children under ten were unvaccinated except one, and out of 42 there were 29 deaths, all the deaths being of unvaccinated children; (3) out of a total of 81 children under fifteen years 57 were unvaccinated and 38 died. Only one death out of the 38 took place in a vaccinated child; of 24 vaccinated children 23 recovered. These facts show the fatality of the disease among young children and the protection afforded by primary vaccination against attack in the first instance and against a fatal result in the second. The protection diminishes progressively after childhood, but the rate of mortality remains enormously higher among the unvaccinated in every age period.

THE results of several series of experimental work in connection with the cultivation of hops were described at the conference of hop-growers held at the South-Eastern Agricultural College last week. The object of the meeting was to receive and discuss the reports of the various experiments upon hops that have been carried out by the College during the past

season. These experiments have in many cases been going on continuously on the same plots since 1895, so that the results are beginning to show a measure of consistency that is not immediately attainable in field trials. Training experiments at Wye are favourable, on the whole, to the systems of wide planting and broad alleys. The umbrella system of training has generally given the maximum weight per acre, but has various disadvantages compared with the Butcher system. Cutting the bine at picking time, as is done when hops are grown on poles or on some wire systems, is found to result in a considerable loss of material to the hop plant, and weakening and loss of crop in the succeeding year. Stripping off the lower leaves and laterals is found to be harmful in seasons of short growth and without effect when the plant is vigorous. Cultivation experiments at Goudhurst, where a plot has now carried a full crop for seven years though without any cultivation beyond surface hoeing, aroused considerable discussion; the trial is to be extended to other soils. Manurial experiments have been carried out on various soils in Kent and Surrey and deal chiefly with the use of mineral manures; the soil is shown to be the main factor in the results attained, especially in the cases where the cultivation has been extended from the typical hoplands to sandy or clay soils.

THE third number of vol. ii. of the *West Indian Bulletin*, just received from Barbados, contains a good deal of useful information relating mainly to cacao and sugar-canes. Mr. Maxwell-Lefroy, entomologist to the Imperial Agricultural Department, has visited the island of Grenada to investigate the prevalence of an insect pest known as "thrips," affecting the leaves and pods of the cacao, and apparently to a less extent the leaves of cashew, guava and Liberian coffee. The insect is found also on cacao in the islands of St. Vincent, St. Lucia and Dominica, but is not known in any other part of the world. Thus far its depredations have not been of a very serious character, and to prevent its becoming a greater plague advice is given to the planters as to the methods which should be adopted to suppress it. Mr. Howard, the mycologist, deals with the fungoid diseases of cacao in the West Indies, summarising the results obtained by the Department in recent investigations. The subject is fully treated in three divisions—pod diseases, stem diseases and root disease. Mr. William G. Freeman, the technical assistant, in a note on the formation of cane-sugar in the sugar-cane, endeavours to give some idea of the possible sequence of events, but more investigation is necessary to clear up many doubtful points—we require to know, for instance, the first product of assimilation and the true relationship to each other of glucose and cane-sugar. Amongst other contributions are Sir W. T. Thiselton-Dyer's note on sugar-cane disease, and Mr. Noël Deerr's article on the distribution of the constituents of the sugar-cane in a Demerara factory and their utilisation as manure. There is an illustrated article on bud variation in the sugar-cane. Information has been collected from the various islands showing the planting and crop seasons of the sugar-cane. A full description of Barbados sour-grass, *Andropogon pertusus*, is given; and the desirability of introducing insectivorous birds from other countries to prey on the insect pests which cause so much destruction in the West Indies is discussed, but the conclusion arrived at seems to be in favour of encouraging the propagation of the local Barbados blackbird and to keep out the East Indian myna or starling, fearing the latter would become a worse pest than the insects.

A PRELIMINARY report of the international balloon ascents of June 13 has just been received. The places from which the ascents were made were Trappes (Paris), Chalais-Meudon, Strassburg, Berlin, Vienna, Pavlovsk (St. Petersburg), Moscow and Bath. In six cases the unmanned balloons were lost, or the records are not forthcoming. The greatest altitude, 14,800 metres, was attained from Trappes, where the lowest temperature, $-51^{\circ}\cdot4$ C., was recorded. The ascent took place about 8h. a.m. temperature at starting, $10^{\circ}\cdot4$, at 6090 m., -25°, at 10,900 m., -50°. At Strassburg the unmanned balloon ascended at 3h. 46 m. p.m., temperature 16°, and went through a thunderstorm cloud; at 2800 m. the temperature was 0°, at 4500 m. -10°, at 5400 m. -15°; the greatest height reached was 5700 m., temperature -17°. Another balloon which ascended about the same time reached an altitude of 10,400 m. and the lowest temperature recorded was $-49^{\circ}\cdot9$. One of the balloons sent up from Berlin reached a height of 9315 m., temperature $-43^{\circ}\cdot5$. From Vienna an unmanned balloon left the earth at 8h. a.m., temperature 22°; at 5000 m. -20°, and at 8900 m. -63° were recorded. Several manned balloons took part in the experiments; one of two from Vienna, carrying Archduke Leopold Salvator and Captain Hinterstoisser, ascended to 3500 metres, where a temperature of -4° was recorded.

MR. C. V. DRYSDALE communicated to the Institution of Electrical Engineers last week a description of a new form of permeameter for testing the magnetic qualities of iron and steel in bulk. A special form of hollow drill is used to drill a hole $\frac{5}{8}$ inch deep in the material to be tested; this hole has its upper part conical, and the small central pin left standing is $\frac{1}{10}$ inch in diameter. Into this hole fits a soft iron plug on the lower part of which are wound the magnetising and testing coils. There is thus formed a miniature permeameter in which nearly the whole of the magnetic circuit is of the material under test. By connecting the coils in the plug with suitably graduated instruments the permeability, retentivity and hysteresis may be very easily tested. Curves and figures which were published showed that the instrument gave very consistent results, although, as was pointed out in the discussion, they did not agree as well as they might with the values usually obtained by other permeameters. But the simplicity of the apparatus and the ease with which a test can be obtained (if, that is, the drills can be made to act with uniform accuracy) should give it considerable commercial value. The dynamo manufacturer requires chiefly a rough guide to the permeability of the casting he is going to use and does not need very rigid scientific accuracy, and such a guide Mr. Drysdale's instrument should be able to provide. In fact, any method which really only tests a very small portion of the bulk, whether *in situ*, as in this case, or after it has been cut off, can never be thoroughly satisfactory.

PROF. LEBEDEW, of Moscow University, describes in Drude's *Annalen der Physik* for November, 1901, a research by means of which he has succeeded in demonstrating experimentally the pressure of light. A translation of his paper is now appearing in the *Electrician*. It followed as a consequence of Maxwell's theory that the combined effect of the electrostatic and electrokinetic stresses is a pressure in the direction of the propagation of the wave numerically equal to the energy in unit volume, and Maxwell pointed out that "the concentrated rays of the electric lamp falling on a thin metallic disc, delicately suspended in a vacuum, might perhaps produce an observable mechanical effect." It was this effect that Sir William Crookes was thought to have obtained in his radiometer, but the magnitude proved many thousand times too great. Prof. Lebedew eliminated the radiometer action by using a large bulb with high exhaustion and by excluding rays capable of heating the tube walls. The radiometer vanes were of very thin aluminium foil suspended by a glass fibre, and the source of light the electric arc. The results obtained agree with the theoretical results of Maxwell within 10 per cent., and show that the pressure is directly proportional to the energy of the incident light and independent of the colour.

A CONCISE handbook of the geology of the city of New York has been published by Mr. L. P. Gratacap, of the American Museum of Natural History.

THE periodic variations of glaciers are dealt with by Dr. S. Finsterwalder and M. E. Muret in the sixth report of the International Commission on Glaciers (*Arch. Sc. Phys. et Nat.* Genève, tome xii., 1901).

"ICE CAVES and Frozen Wells as Meteorological Phenomena" is the title of a paper by Mr. H. H. Kimball (*Monthly Weather Review*, August 1901). The author's observations were made in New York co. and Vermont, and he concludes that the phenomena are due to the cold air of winter circulating to unusual depths below the surface and freezing the small quantity of water with which it comes in contact. The ice may not entirely disappear during the following summer, but continue under certain conditions to accumulate for ages.

IN the Memoirs of the Geological Survey of India (vol. xxxi. part ii., 1901) there is a geological sketch of the Baluchistan Desert and part of eastern Persia, by Mr. E. Vredenburg. The rocks comprise marine strata ranging in age from Upper Cretaceous to Upper Eocene. Interbedded with them is a large proportion of volcanic rocks, and these, together with numerous igneous intrusions, form the chief hill masses. Considerable areas are occupied by Siwalik strata, land deposits of Miocene age, which consist of conglomerates, friable sandstones, and clays frequently white or brightly coloured in various tints of pale terra-cotta, ochre or green. Much of the low ground is concealed by modern alluvium and sand dunes. Except in the unusual event of a storm the plains are absolutely dry, and when such an occurrence takes place the flood seldom lasts more than an hour. Then the water rushes through a network of irregular and ever-shifting furrows, rolling along with it large boulders which rattle loudly as they come into collision. These floods by their suddenness constitute a source of danger to the flocks, especially to sheep and goats, which may be carried away if not driven off in time by the shepherds. In the western portion of the country examined there are several recent volcanoes, one of which still shows signs of activity.

THE artesian waters of Australia were dealt with by Mr. J. P. Thomson in a paper read at a recent meeting of the Royal Geographical Society of Australia. Although the whole of the Australian colonies have taken an active part in the somewhat minute and altogether elaborate search for artesian water, it is to Queensland that the greatest credit is due for having discovered the existence of an unlimited and practically inexhaustible supply in the lower cretaceous formation that underlies the vast rolling downs of the western portion of that State. Several of the inland towns and many parts of the western district are now watered by numerous artesian wells or bores. In some remarks upon the subject, the president of the Society, Sir Hugh Nelson, pointed out that up to the present time the amount of artesian water brought to the surface at the bores has had very little effect as an irrigating agent upon the great areas of land in the west during seasons of drought. This water is valuable for drinking purposes for stock, but stock cannot exist upon water alone—they require herbage, and the supply of water is not plentiful enough to irrigate the runs. The Hon. A. C. Gregory also explained that artesian water contains a small percentage of saline matter, and while it might be used for irrigating small areas of cultivation the saline properties of the water have the reverse of a beneficial effect upon the land when the water is used to irrigate large tracts of country.

WE have received a copy of "A Catalogue of Crustacea and Pycnogonida in the Museum of University College, Dundee," by Prof. d'Arcy W. Thompson. The list is a long one.

THE Egyptian Government has just issued a series of "Notes for Travellers and Sportsmen in the Sudan." These give full information with regard to the game of the country and the conditions under which it may be killed. The regulations for the protection of the rarer species seem well calculated to attain the end in view—at least for a time.

THE nesting and other habits of one of the North American cat-fishes of the genus Amiurus forms the subject of a paper, by Mr. A. C. Eycleshymer, in the *American Naturalist* for November. "Although repeated efforts were made," writes the author, "to find the nests, they were unsuccessful until June 8, 1896, when three nests were found in Fowler Lake, Wisconsin. Two of these were in pieces of stovepipe, the third in an old pail. The nests were in clear water, near a bold rocky shore, and at a depth of four or five feet; all contained embryos, and each was guarded by a parent fish—which one I did not ascertain."

THE latest issue of the *Zeitschrift für Wissenschaftliche Zoologie* (vol. lxx. pt. iii.) contains two papers, one, by Dr. R. Hesse, on the eyes of arthropods (being the seventh of a series on the visual organs of invertebrates), and the second, by Herr C. Rabl, on the origin of limbs. In the latter memoir much attention is devoted to the question whether fins, as Gegenbaur thought, are derived from modified gill-arches, or whether, as suggested by Balfour and Thacher, from lateral folds, the author favouring the latter view. The diagrams illustrating the various modifications of carpal and tarsal structure in the lower vertebrates are especially interesting.

To the November number of the *American Naturalist* Mr. H. L. Osborne communicates some interesting notes on axolotls from Colorado and Dakota. Two kinds of metamorphosis occur during the passage of these creatures from an aquatic to a terrestrial existence, first of all in the development of the limbs and lungs, the alteration of the circulatory system and the maturation of the reproductive organs. But there are also secondary changes, which may occur either early or late in life. In some districts axolotls pass into the adult amblystoma state when quite small; but in Mexico the secondary changes never take place at all, so that the animal, although adult in other respects, remains in the aquatic condition throughout life.

AN important paper in the November issue of the *Quarterly Journal of Microscopical Science* is one by Mr. E. S. Goodrich on the pelvic girdle and fins of the "fringe-finned ganoid" fish Eusthenopteron. The specimen on which the communication is based is from the Devonian of Canada, and is preserved in the British Museum. It is remarkable as being the only known example among the numerous remains of the extinct representatives of the group in question in which the pelvis and fins are preserved in a complete state and showing their natural relations to one another. Although the structure of the fin-rays shows a curious approximation to the type of the more specialised modern bony fishes, in other respects the pelvic fins of this fish show signs of being derived from a type allied to that which persists in the Queensland lung-fish (Ceratodus). Another article in the same journal, by Mr. E. P. Allis, deals with certain parts of the anatomy of the small shark known as *Mustelus laevis*.

THE *Transactions* of the New Zealand Institute for 1900 contain a large number of papers on the zoology of the colony, as well as others connected with acclimatisation and stock-breeding. Among the former, reference may be made to Prof. Benham's description of the New Zealand lancelet, of which only two examples appear to be known. This form is now referred to the genus Heteropleuron, the commonest type of the group in the southern hemisphere, under the name of *H. hectori*. In

two other communications the same writer discusses the New Zealand earthworms, describing three new species, under as many generic heads. Prof. Dendy and Miss Olliver jointly describe a new freshwater leech of the genus Glossiphonia, while the former contributes a fourth paper on the land planarians of the colony.

THE acclimatisation and variation of Salmonidæ in New Zealand form the subject of a paper in the *Transactions* of the New Zealand Institute for 1900 by Mr. A. J. Rutherfurd, in which it is concluded that greater success is likely to attend the introduction of the north Pacific salmonoids than that of *Salmo salar*, which is a more delicate fish, unlikely to find what it requires in an ocean so far removed from its native habitat. In regard to trout, the author is of opinion that "whatever variety we liberate of the ordinary species of trout, it will develop into a *Salmo novae-zealandiae*, suited to the water in which it is liberated, and corresponding with trout in similar localities in the Northern Hemisphere more closely than with the varieties found in the more northern latitudes of our mother-country." Considerable interest also attaches to a paper by Mr. T. White on breeding black merinoes, of which there are now several flocks in the colony. Although the wool does not fetch so high a price as the best selected white it is really more valuable, as the price is the same for the whole fleece.

A CIRCULAR which we have just received from Messrs. Hirschberg and Oestergaard, Berlin, provides us with another example of German enterprise. This firm has produced a large wall map of the British Isles and of the world, showing the British colonies in a distinctive colour, and special offers are being made to English newspapers to take up the map and sell it to their readers. The map is 53 in. by 42 and is printed in twelve colours. In a space left at the top the title of the newspaper adopting the map, and other particulars of local interest, will be inserted as desired. As a number of newspapers have taken up the map there is apparently no objection to its German origin. But how is it that our geographical publishers cannot make similar arrangements with newspapers, and so prevent, in a sense, the war from being carried into our own country? It certainly seems strange that Germany should find it worth while to supply us with cheap maps of the British Isles and the Empire.

THE "Year Book of the Scientific and Learned Societies" (London: C. Griffin and Co., Ltd.) is a very handy guide to organisations existing in the British Isles for the promotion of knowledge. The societies and other institutions are arranged in fourteen different departments, according to their objects, and particulars are given as to officers, meetings, conditions of membership, and publications of each. In addition, lists are given of papers read before each society from January, 1900, to June of the present year. The reason why the papers read during eighteen months are catalogued instead of those read in a calendar year is that it is intended in future to make the Year Book correspond as closely as possible with the sessional year of the societies dealt with in it. Subsequent volumes will therefore record the papers read before each society between September and June, and they will be published as early as possible in the succeeding session. This change will be an additional convenience to those who use the Year Book as a manual of ready reference or a general review of Great Britain's annual contributions to scientific knowledge.

THE work of John Mayow, a pupil of Robert Boyle, was touched upon by Dr. J. B. Cohen, in an address recently delivered before the Yorkshire College Scientific Society. Mayow was certainly a genius, and some of his observations are remarkable for their shrewdness and depth, but they have often been misrepresented, and Dr. Cohen gives some interpretations of them which should interest students of the history of chemistry. His treatise on combustion was completed before the birth of the phlogiston theory, and was revived a century later, after Priestley had discovered oxygen, and the phlogiston theory was breaking down. Referring to Mayow's experiments on hydrogen and nitric oxide, Dr. Cohen remarks, "it must suffice to say that he anticipated Priestley in recognising both these as distinct kinds of gases, differing from, but possessing the same elasticity as air. Although Priestley's view of the composition of dephlogisticated air has much in common with that of Mayow's nitro-aërial particles, there is plenty of evidence to show that Priestley's ideas were formed quite independently. It must be admitted, however, that they show little advance on those of a whole century before."

THE recent work of M. Moissan on the properties of pure calcium has shown that the description of this element current in the text-books was by no means an accurate one, and from the work of M. Guntz, published in the current number of the *Comptes rendus*, it would appear that the properties of pure barium also differ considerably from those hitherto assigned to it. The starting point of the work is barium amalgam, and by the electrolysis of a saturated solution of barium chloride with a mercury kathode it would appear to be quite easy to prepare several kilograms of a 3 per cent. barium amalgam. It is the separation of the mercury from this amalgam which has proved to be such a difficult matter. M. Maquenne, for instance, who attempted to distil off the mercury, was quite unable to obtain a coherent ingot of barium in this way. M. Guntz has found that the secret of success in this experiment is to apply the heating gradually; the amalgam is placed in an iron boat in a wide porcelain tube and the tube heated by a coil of fine platinum wire, brasqued by a protecting coating of alumina and magnesia. By means of this electric furnace it has been found possible to raise the temperature as slowly as 200° C. per hour, and finally to maintain the tube, 50 mm. in diameter and 300 mm. long, at 1200° to 1300° C., with an expenditure of 600 to 700 watts. Working in this way a good yield of pure barium has been obtained at 1000° C. The barium thus obtained when freshly cut has a white silvery lustre; it is soft, a little harder than lead, and is extremely oxidisable in the air, often catching fire when attempting to remove it from the boat by means of a hard body. It resembles lithium and calcium in dissolving in liquid ammonia, and attacks easily water, alcohol and even an alcoholic solution of baryta.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Dr. A. E. Neale; two Short-eared Owls (*Asio brachyotus*), one Short-eared Owl (*Asio brachyotus*), European, presented respectively by Mr. W. Jamrach and Mr. C. W. Burnett; a Variegated Sheldrake (*Tadorna variegata*) from New Zealand, purchased.

OUR ASTRONOMICAL COLUMN.

THE NEW STAR IN PERSEUS.—Sir Norman Lockyer recently communicated to the Royal Society some further observations of the new star in Perseus made at the Solar Physics Observatory in continuation of the last previously recorded (Roy. Soc. *Proc.*, vol. lxviii. p. 399). In the present paper, which brings the information up to the end of September, it is first pointed out that the short period light variations have ceased and that the Nova was gradually becoming fainter, reaching about magnitude 6·7. In the visual spectrum the nebular line at wave-length 5007 was the strongest. Photographs of the spectrum showed that since last April a great change has taken place. The lines then were very broad and ill defined, but are now much narrower with better defined edges. The lines of hydrogen, which were the strongest in the spectrum have become comparatively very

weak. Other lines have made their appearance, the strongest of which are 3868 and 3970, 4364 and 4720. The first is an unknown line strong in the spectra of planetary nebulæ, while the other three are of unknown origin. It is suggested that the second line (3970λ) is not the line of hydrogen at Hε, as the other hydrogen lines in the spectrum are so weak. There is, further, a new line in the ultra-violet at wave-length 342 (about), which Gothard has independently recorded. It is interesting to note that the new gas lines show a structure somewhat similar to that of the hydrogen lines in earlier photographs. The enhanced lines of iron, magnesium, &c., which were such a conspicuous feature of the first photographs, have entirely disappeared, and the probability is that the bright lines now, other than hydrogen and helium, belong to gases the terrestrial equivalents of which have not been found.

VARIATION OF LATITUDE.—Prof. S. C. Chandler has made an exhaustive examination of the old records obtained with the reflex zenith tube at Greenwich from 1852–82, which were abandoned as being affected with undiscoverable sources of instrumental error, and finds that for the periods providing continuous measures throughout the year they yield most valuable data for the determination of latitude variation, and that this anomaly, unknown at the time, was most probably the cause of the want of agreement among the observations. The two periods yielding continuous values were 1857–63 and 1864–70 (*Astronomical Journal*, vol. xxii., No. 511.)

DETERMINATION OF THE ELEVATION OF METEORS.—During the rather brilliant display of Perseids in August last a series of successful experiments was made by the observers at Juvisy Observatory to determine the heights of as many meteors as possible. Two stations, Juvisy and Croix-de-Berny (Antony), were chosen at a distance of 9·200 km. The number of meteors registered at both stations was 21, of which 8 fulfilled all the necessary conditions for the determination, and a table is given showing their calculated heights of appearance and disappearance, and also the resulting length of trajectory. The lowest record is 15 km. and the highest 119 km. (*Bulletin de la Société Astronomique de France*, November 1901.)

MERIDIAN OBSERVATIONS AT HARVARD COLLEGE OBSERVATORY.—In a separately published portion of vol. xli. of the *Annals of Harvard College Observatory* (No. 7, pp. 189–211) Mr. A. Searle gives an account of a series of special investigations which have been in progress with the hope of eliminating several systematic errors in the transit observations. It was thought that these might be due to the employment of ruled glass plates instead of spider threads, and for a time the latter have been substituted for trial. The result showed that the change produced no important difference in the discrepancies referred to. Personal equation with respect to magnitude was noticeable in both right ascension and declination when the transits were taken over inclined lines, as was the case with the ruled glass plates formerly used.

LENGTH OF THE TERRESTRIAL DAY.—Mr. R. S. Woodward has been investigating the extent to which the secular cooling of the earth and the fall of meteoric dust may affect the length of the terrestrial day. Attention is first drawn to the conclusion of Laplace that the day has not changed appreciably owing to secular cooling during the past 2000 years, but this was on the assumption that the earth is in the last stages of cooling. This the present author thinks an unnecessary and doubtful restriction, and proceeds, using the other conditions identical with those of Laplace, to develop a method of determining the effect on the length of day of the cubical contraction of the earth during any portion of, or during the entire history of, the process of secular cooling.

It is suggested that, contrary to the views of Laplace, Fourier and Poisson, the dissipation of the internal heat of the earth is not controlled by the atmosphere and oceans, but escapes as if they did not exist.

The main conclusion is that in the entire history of secular cooling of the earth the day may be shortened from this cause by as much as 6 per cent. of its original length. With respect to a definite time variation, it is concluded that the length of the day will not change, or has not changed, as the case may be, by so much as half a second in the first ten million years after the initial epoch.

The concluding portion of the paper deals with the effect of accumulations of meteoric dust. The distribution is assumed as uniform over the surface. Taking Newton's estimate of the number of meteorites falling daily, it is calculated that at least a million million years would elapse before a change of a quarter of a second would be produced. The effect of secular cooling is thus considerably more than that of meteoric accumulations. (*Astronomical Journal*, vol. xxi, No. 502).

PHYSIOLOGY AT THE BRITISH ASSOCIATION.

THE Section of Physiology was presided over by Prof. McKendrick, F.R.S., and the place of meeting was Prof. McKendrick's laboratory at the University. Despite the near approach of the date of the fifth triennial International meeting of Physiologists held at Turin in September, the Section was well attended by working physiologists, and the audiences were often large. Profs. Schäfer and Sherrington were vice-presidents, and amongst others contributing to the meetings were Sir Michael Foster, Sir John Sanderson, Dr. Theodore Beer, Dr. Brodie, Miss F. Buchanan, Dr. Burch, Prof. Gotch, Dr. A. A. Gray, Dr. Edridge Green, Prof. Marcus Hartog, Dr. Kennedy, Dr. Myers, Dr. Noel Paton, Prof. Waymouth Reid, Dr. W. H. R. Rivers, Prof. W. H. Thompson, and Dr. J. A. Wanklyn.

The proceedings of the Section commenced with the president's address. Prof. McKendrick took for his theme the relation of physical and chemical structure as understood at present to our conception of the structure of living matter. The president commenced by pointing to the progress which had been made by physiology in the quarter of a century that had elapsed since the previous meeting at Glasgow. Physiology in its progress had proven itself a living and logical inductive science grappling successfully with its problems by help of the same laws that physics and chemistry apply to non-living matter and its phenomena. In this respect it contrasted strikingly with subjects, *e.g.* human anatomy, which had been closely associated with it formerly in educational curricula.

Physiology had in the last quarter of the century proved fruitful of discovery to an astonishing extent. Many of its discoveries were of high practical value to medicine as well as of theoretical value. It had struck deep into the soil, acquiring many new data of extreme accuracy and obtaining much profounder insight in the concatenations of the machinery of life. The phenomena of muscular contraction—that prime event in biodynamics,—the process of secretion by gland cells, the mutual synergy of organs as illustrated by internal secretion, the functional architecture of the nervous system, the mechanics of rejuvenescence of protoplasm by sexual recombination (fertilisation), all these branches of the physiological tree of knowledge had, under the cultivation of the last five and twenty years, grown vastly in extent and yielded blossom and invaluable fruit. Facts more accurate and theories more profound had drawn their science closer to the elder sister sciences of more exact measurement and at the same time had created, it must be admitted, a gap between it and subjects with which it had formerly been usually associated in teaching. It had widened the educational field and educational worth of physiology, releasing it from former restriction to narrower technical applications. Save in mathematics, knowledge cannot be absolute in any domain of natural science. Physiology shared with the sister sciences their birthright of problems that were, to speak in paradox, the more insoluble the further one progressed toward their solution.

The animal body—the human body—was a machine of high complexity, constituted of many interrelated parts, called organs, the "simple" tissues and the "compound" tissues. A number of its phenomena had indubitably received their lasting explanation; but the difficulty of examining the machinery of living matter while still in living action was extreme. The first step of the chemist's analysis was to kill the substance; yet his goal was analysis of matter still alive. A number of thoughtful physiologists had returned in recent years to study of the unit of physiological structure, the cell. For the study of the phenomena of life an object more suitable than the undifferentiated single independently living cell was in many cases a simple tissue composed of numbers of such cells associated and highly differentiated, but all differentiated in the same way one as another. Hence the tendency of the modern physiologist to examine the powers and reactions of the simple tissues rather than of unicellular organisms such as amœba. It must be admitted, however, that in spite of all their labour in many respects their knowledge had not yet reached far. For

instance, the visible details of structure revealed in the cell by the most perfect modern microscopes in collaboration with all the elaborate technique of modern histology seemed to bring us in no perceptible degree nearer towards an explanation of the chemical and physical construction of the cell. But if the matter were considered fully it became evident that the phenomena of life depend on changes occurring in the interactions of particles of matter far too small even to be seen by the strongest magnification yet obtainable by microscopes.

The physicist and chemist had not been content, it was pointed out, with the investigation of large masses of dead matter. To explain many of the phenomena they met with they had had recourse to the conceptions of molecules and atoms and to the formulation of laws that regulate the movements of these units almost infinitely small. The conception of the characters and dimensions of the molecules of *living* matter had occupied certain of the astutest physicists. Clerk Maxwell had placed before the physiologist a curious dilemma. Either the germ could not be homogeneous, developing as it does into a complex being with its hundred thousand characteristics, or if structurally diverse it is so small that its number of parts is insufficient to give a basis for the development of all the characteristics inherent in and developed by it as it expands into the adult creature. Only another supposition was postulable, namely that the germ was not a material system entirely; the adoption of that last supposition was, of course, equivalent to resigning the problem as inaccessible to any method obtaining in natural science.

If, however, in the light of twenty-five years of additional knowledge since the time of Clerk Maxwell the problem were reexamined we were not led necessarily to the dilemma he propounded. A quarter of a century ago it seemed to so competent an inquirer as he that the number of organic molecules in the fertilised ovum would be too few to account for the transmission of hereditary peculiarities. It then seemed that the molecules would not amount to a million in number. But to-day, Prof. McKendrick urged, it was reasonable from existing data to suppose that the germinal vesicle might contain a million of millions of organic molecules. Complex arrangements of these molecules suited for the development of all the parts of a highly complicated organism might satisfy all the demands of the theory of heredity. Doubtless the germ was a material system through and through. The conception of the physicist was that molecules were in various states of movement; and the thinkers were striving toward a kinetic theory of molecules and of atoms of solid matter which might be as fruitful as the kinetic theory of gases. There were motions atomic and molecular. It was conceivable that the peculiarities of vital action might be determined by the kind of motion that took place in the molecules of what we call living matter. It might be different in kind from some of the motions dealt with by physicists. Life is continually being created from non-living material; such, at least, is the existing view of growth by the assimilation of food. The creation of living matter out of non-living may be the transmission to the dead matter of molecular motions which are *sui generis* in form.

Sir John Burdon Sanderson opened the ordinary work of the Section by communicating a paper on the use of the telephone for investigating the rhythmic phenomena of muscles. The communication was largely based on the recent researches of Miss Florence Buchanan. Sir John explained that it was well known that violent contractions of muscle are sometimes obviously rhythmical. The muscular rhythm he should deal with was of a different kind and seat of production to that of violent willed action. The latter had its origin in the rhythmic discharge of nerve-centres. But the muscles themselves seemed to respond rhythmically, not continuously, to even continuous excitation. Their rate of rhythm was of much higher frequency than that of the nervous system; it amounted to repetitions amounting to about 100 per second. The rhythmic variation in the contracting elements of the muscle was variation of, amongst other states, that of electrical tension. Wedenskii, of St. Petersburg, had used the telephone for investigation of this condition of the muscle. A certain note might be low, *e.g.*, A in the bass clef, and if they applied stimuli to the muscle at something like the rate of that pitch they could force the muscle to harmonise. If the stimuli were regulated to G instead of A it would correspond with G, if with B instead of A, with B. But if the frequency were increased to much higher the muscle showed the same response as before—they had always about the same note. The muscle had, therefore, within limits a period of phasic activity of its own.

The next communication made, on behalf of Dr. A. S. Grünbaum (Liverpool) and himself, by Prof. Sherrington (Liverpool), dealt with experiments on the brain of the chimpanzee. The brain of the chimpanzee is, after that of the gorilla, the brain which approaches most nearly to that of man himself. The experiments undertaken had been the ablation of certain portions of the cortex with the view to study the after effects upon the behaviour and movements of the animals observed. The cerebral cortical centre for the right hand had first been carefully exposed and delimited by excitation with faradic currents. All that region of the cortex which had under excitation provoked movement commencing in the right hand had then been destroyed. The immediate effect of the injury had been paralysis of the hand, with a less degree of paralysis of the wrist and shoulder. In the course of five weeks, however, recovery had been so marked as to restore to the hand its uses almost completely, as far as mere inspection could decide. The animal often used the hand and sometimes fed itself on fruit, &c., from it alone, without use at all of the left hand. The right arm had in the course of even a fortnight recovered its use for climbing, &c. Examination of the spinal cord for the degeneration of tracts following this lesion led to the discovery of an anthropoid feature in the cord not previously found in any spinal cord except the human, namely, a fully-developed "direct pyramidal" tract. In another individual a limited destruction of the cerebral cortex in the leg-region of the "motor" area produced at once severe but short-lasting paralysis of the leg, with immediate increase of the knee jerk. The paralysis seemed in the course of four weeks to have passed away, although there still remained marked exaggeration of the knee jerk. The spinal degeneration when examined revealed no direct pyramidal tract in this case: either, therefore, the existence of that tract is subject to great individual variation or the tract is not connected with the more mesial portion of the motor area. Ablation of the posterior part of the left inferior frontal convolution did not produce any obvious alteration either of the character or of the amount of the vocal sounds uttered by the animal. The animal "talked" as much and apparently as variedly after as before the cortical lesion. Regarding descending tracts which degenerated in the spinal cord after lesions of the cortex it was noteworthy that the lesions which produced spinal degeneration were in every case situate in front of the fissure of Rolando. A further point of interest was that the degeneration descending from lesion of the hand area extended down along the spinal cord as far as the top of the lumbar region. Microscopic specimens were demonstrated in illustration of these points.

Dr. Edridge-Green followed with a paper on colour-vision. He developed his well-known views on the classification of the various types of colour blindness. He urged the unsatisfactory character of the test followed in using Hohngren's coloured wools, and the advantage of replacing that test officially by a lantern-test. Dr. J. Wanklyn read a paper on arsenical pigmentation of the skin, and Dr. W. A. Osborn recounted observations on the physical properties of caseinogen salts in solution.

On Friday, September 13, the proceedings opened by a most lucid and interesting paper by Prof. McKendrick on the registration of sounds. His description was richly illustrated both pictorially and by experiment. It proceeded to deal with the subject in its historical development. The methods adopted for the registration of speech sounds from 1875 onwards were shown. The gradual evolution of the phonograph was traced, and of the methods employed for the analysis of the marks made upon the wax cylinder of that instrument. There were special characteristics about vocal sounds which distinguished them from all the sounds of musical instruments. Language would come to be recorded, not by such symbols as are used at present for words and syllables, but by less arbitrary and more reasoned systems. It had been suggested that the signs should indicate what had to be done by the vocal and articulating organs for the production of any given sound. Prof. McKendrick then examined the various theories put forward regarding the formation of vowel sounds. He spoke especially of the recent researches of Dr. Marès, of the Physiological Institute of the Sorbonne, Paris. Marès had approached the problem from a very original point of view, regarding the grouping of the vibrations, in the internal sequence rather than the external sequence, as of main influence. Using a syren with plates per-

forated according to the sequences observed in the flame pictures, &c., of vowel sounds and adding to the syren certain resonators which were faithfully moulded on the shapes taken by the mouth in utterance of vowels, Marès had succeeded in reproducing the vowel sounds with a degree of fidelity surpassing those of all previous efforts. Prof. McKendrick urged the phonographic registration of dialects. Such a collection of phonographic records would be of help to the science of language. How little could we tell to-day of the spoken sounds of ancient Sanskrit, of how Demosthenes spoke in Greek or Cicero in Latin; how little also of the exact accent of Shakspeare's English. Finally, a demonstration was given of the practical efficiency of the intensification of the sounds of a phonograph by causing their waves to fall upon a microphone and that instrument in turn to affect a loud-speaking telephone.

Dr. R. Kennedy (Glasgow) read a paper on return of voluntary movements after alteration of the nerve-supply by nerve-crossing or anastomosis. His experiments on animals had shown that when the nerve supplying the flexor muscles of a limb were divided and cross-united to the nerves supplying the extensor muscles, the animal in time regained the functional use of the limb, although the innervation of the muscle groups was reversed. The nerve-centres for the flexor and extensor muscles interchanged their positions and could be thrown into appropriate activity for the crossed relations of the muscles. This principle of nerve-crossing found a practical application in many cases of paralysis of a muscle or group of muscles supplied by a particular nerve. A portion of the nerve below the lesion could be grafted on to a neighbouring normal nerve with probability of restoration of the function of the paralysed muscles. Photographs were shown of a case of facial spasm which he had relieved by dividing the facial nerve and grafting its distal end on to the spinal accessory. The result had been return of normal voluntary movement in the face and absence of spasm. But movements of the face tended to occur as an accompaniment of certain movements of the arm.

Prof. Waymouth Reid, F.R.S. (Dundee), discussed the question "Can solutions of Native Proteids exert Osmotic Pressure?" Of the two methods of testing this question, namely, cryoscopy and direct measurement against a membrane impermeable to proteid, the latter alone is likely to lead to a satisfactory answer. Against the cryoscopic method would be the high molecular weight and errors due to traces of salts not fully eliminable by observation on solution of the ash. The method of direct measurement is liable to error in the possibility of presence of a contamination (not salts) which, like proteid, cannot pass the membrane, and so if in solution exerting osmotic pressure. A true finding on the point is only likely to be reached by working with "solutions" of pure proteid. The experiments of Starling with blood serum led to variable results, the osmotic pressure for the 1 per cent. concentration of the proteids in their native fluid being given as from 2·97 to 5·29 mm. Hg. at room temperatures. These experiments prove that substances exist in solution in serum to which a gelatine membrane is impermeable, but they do not prove that the osmotic pressure observed is due to the proteid constituent either in part or *in toto*. The proteid might be inactive *quâ* production of osmotic pressure, and some other constituent of serum in solution might be responsible. A well-dialysed solution of once crystallised horse serum-albumin gave osmotic pressure on a formalised gelatine membrane against distilled water in a rocking osmometer, a pressure which after fourteen days had settled to 15·5 mm. Hg. for the 1 per cent. concentration of proteid. The pressure remained constant at this level for another six days (*i.e.* until the twenty-first day of experiment), after which the observation was stopped. Had the experiment been stopped six days after the start the estimate of osmotic pressure would have been 28 mm. of mercury for the 1 per cent. concentration of proteid, a level at which it stood constant till the ninth day. The membrane was proved impermeable to proteid by the ordinary tests, but the preparation of serum-albumin was also proved impure, for it held more than 17 per cent. of nitrogen.

Ovalbumin is so readily crystallised and recrystallised by Hopkins' modification of the Hofmeister method that we can probably assure ourselves of the purity of this proteid better than of that of any other from an animal source.

With "solutions" of recrystallised and well-washed ovalbumin (15·41 per cent. of nitrogen) no pressure can be got on a natural or formalised gelatine membrane, proved (at the end of the experiment) impermeable to the proteid.

Dilute "white of egg" in contrast gives a lasting pressure against its filtrate through a gelatine filter, at similar concentration in proteid. The addition of sodic hydrate to the "solution" of ovalbumin, within the limits of appearance of alkalinity to litmus or phenolphthalein, does not affect the negative result.

Finally, a "solution" of crystallised hemp-seed globulin in sodic chloride solution put against the original salt solution gave no pressure on a gelatine membrane proved impermeable to the globulin at the end of the experiment.

If these experimental results are borne out by those still in progress, the conclusion of many will be strengthened, viz. that such so-called solutions are only suspensions, since the power to exert osmotic pressure on a suitable membrane is our most convincing test of solution in the case of a non-electrolyte.

Prof. Waymouth Reid also read a contribution to the study of ionic effects as exemplified in the small intestine. The action of salts in solution upon various vital phenomena has long been studied, but the subject is prominent just now as a result of the brilliant experiments of Prof. Loeb and his pupils.

From a general point of view his more important conclusions are:—

(1) Several different metallic ions are necessary for the exhibition of vital phenomena, and the nature of these and their optimum relative proportions vary in different tissues and classes of vital phenomena, even in one and the same animal.

(2) One can impart to a living tissue new properties by changing the quality and the relative proportions of the ions in it.

The sodium ion is the most active in starting rhythmical construction of skeletal muscle, but other ions must be present in addition, otherwise by mere excess the sodium becomes a poison.

Again, we cannot reason from the action of a given ion upon one tissue to its action on another, even if the second tissue performs functions which are superficially analogous.

Thus Lillie observed that in the larva of *Arenicola cristata* ciliary motion continued in solutions of calcium, magnesium and potassium salts which stopped the activity of the muscles of the body, while contraction of the body-muscles continued in solutions of sodium salt which stopped the motion of the cilia.

Potassium ions, so poisonous to cardiac muscle, may be beneficial to the action of other protoplasms. Loeb found that the early development of *Fundulus* embryos was favoured by potassium ions up till the formation of the heart.

In the eggs of the marine annelid *Chaetopterus*, which when unfertilised do not develop in sea-water, an artificial parthenogenesis can be started by potassium ions, and the action is ionic and not osmotic as in some parthenogeneses. Here the potassium ion acts as a specific stimulant. One would expect that if the cells of the mammalian intestine take an active part in the process of absorption a variation of the preponderating ion in the solution of the substance the absorption of which is being studied might affect the absorption of the substance by the gut wall.

In the experiments glucose was selected for study since it is normal to the intestine and capable of fairly accurate estimation, and the absorption of isotonic solutions of glucose in sodium and potassium chloride solutions were compared.

The results so far have indicated that a preponderance of the potassium ion over the sodium ion favours the uptake of glucose, about half as much again of the glucose being absorbed from solutions holding potassium chloride as from solutions of equal molecular concentration holding sodium chloride.

Unfortunately, the ionic effect can only be studied, in this case, from the cavity side of the membrane, on account of the highly poisonous action of potassium upon the heart muscle when exhibited in the circulating blood. Experiments with other ions were in progress.

Dr. Albert A. Gray (Glasgow) read a paper on some methods of preparation of the inner ear, with remarks on its function. He showed a new method of preparing the membranous ear by first supporting the structure and then destroying the surrounding bone. From these preparations he drew inferences regarding the phenomena of giddiness and of the theories of hearing. A preparation was shown of the entire internal ear. After first embedding preparations in a firm substance the surrounding bone was decalcified by nitric acid, and the whole was rendered transparent by oil of thyme. The demonstration of the upward increase in width of the ligamentum spirale of the cochlea was a matter on which Dr. Gray especially laid stress.

Dr. Noel Paton (Edinburgh) gave on behalf of himself and Drs. Gulland and Fowler some account of experiments in examination of the asserted hæmatopoietic functions of the spleen. His previous work had shown that the spleen exerted no

detected influence upon the course of chemical digestive changes in mammals. The question remained, "Is the spleen connected with production of blood corpuscles?" The methods he and his colleagues had employed were (1) comparison of corpuscles in blood entering and leaving the spleen; (2) effect of removal of spleen on number of blood corpuscles; (3) the rate of recovery of the number of corpuscles in animals with and in animals without spleen after hæmorrhages and after hæmolytics.

The results obtained by these methods were:—(1) No difference observed in blood of splenic vein and splenic artery. Rollett's well-known statement in Stricker's "Handbuch" of the great relative increase of leucocytes in the blood of the splenic vein was therefore not confirmed. (2) Removal of the spleen (dog, rabbit, cat) produced no perceptible change in the number of corpuscles in the blood. (3) Recovery of number of corpuscles after hæmorrhage and hæmolytics proceeded as fast in the animals without spleen as in those with spleen.

Dr. W. Brodie Brodie (Glasgow) made a communication on the action of oxalates on the calcium of muscle. From a series of observations made it was argued (1) that the action of oxalates in destroying muscular irritability was only manifest when the muscle was thrown into repeated contractions; (2) that the irritability of resting muscles was not injured by oxalates; (3) that it was probable that calcium was liberated from a complex compound when the muscle entered into contraction.

Dr. W. H. R. Rivers (Cambridge) communicated the results of testing the vision of natives of Murray Island and that of a number of English people with the visual illusion known as the Müller-Lyer. This well-known illusion is one in which additional straight lines lengthen or shorten in appearance an original straight line according to the inclination of the direction toward it. By means of a slide the line could be made of the same length as a standard line. Observations were carried out on forty-two English people and thirty-eight natives of Murray Island, between New Guinea and Australia. Each person made ten trials. The standard line measured 75 millimetres; to the average English person the line compared with it appeared equal to it when of 53 millimetres length. The average Murray Islander made the line 60 millimetres, so that the illusion was less pronounced with him than with the average English observer. There was marked agreement among the Murray Island men, who were as uncultured and unskilled in the European sense as any population could be. The Murray Islanders, though they could be regarded as savages, were yet able to make these observations very well. When Dr. Rivers went out on his expedition he anticipated great difficulty in getting people of that degree of civilisation to enter into the making of such observations. He had, however, in fact found that they made them with even more attentiveness than the average Englishman could be induced to give to the test. The English individuals tested could be divided into two classes, those acquainted with the illusion, such as students of psycho-physiology, and those who were roughly acquainted with it through the advertisements of soap manufacturers, &c. It was interesting that the results obtained from both these classes were practically the same. The English individual when told to make the two lines equal as he saw them no doubt sometimes involuntarily corrected to some extent the tendency developed in the illusion. The Murray Islanders gave more consistent results than the Europeans. This greater consistence may have been due to the total ignorance by the Islanders and their thus remaining uninfluenced by speculation founded on knowledge of the illusion. Prof. McKendrick, in thanking Dr. Rivers for his valuable communication, urged the great interest, both practical and theoretical, of the labour of psycho-physiologists. At present the labour was chiefly the accumulation of facts many of which as yet were difficult to coordinate into general laws. It was exceedingly important that the subject should be seriously taken up in this country. In the American schools a great deal of useful progress was being made.

On Tuesday, September 17, Dr. C. S. Myers (Cambridge) communicated the results of a series of observations made with Galton's whistle upon the hearing of the Murray Islanders and some inhabitants of Buchan, Aberdeenshire. The result showed that the Murray Islanders could not at any age hear such high-pitched notes as the people of Buchan. The latter had from childhood upward a finer perception for high-pitched notes than the former.

Prof. Marcus Hartog demonstrated a model showing the mechanism of the frog's tongue.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 230th meeting of the Junior Scientific Club was held on November 29. Dr. Gustav Mann (New College) read a paper on the theory of dyeing and staining, and Mr. D. A. Gilchrist one on agricultural experiments at Reading and in Canada.

Mr. A. J. Jenkinson, of Hertford College, has been elected to the John Locke scholarship in mental philosophy.

Mr. G. W. S. Farmer, of Balliol College, has been appointed Litchfield lecturer in clinical surgery for two years.

CAMBRIDGE.—The Allen scholarship for research in medicine, mathematics, physics and chemistry, biology and geology, or moral science, will be awarded in the ensuing Lent Term. The emolument of the student is 250*l*. for one year. Any graduate of the University is eligible, provided he is not more than twenty-eight years of age on January 8, 1902. Candidates must send their names, with a definite statement of the course of research they propose to undertake, to the Vice-Chancellor by February 1, 1902.

THE annual prize distribution and members' and students' conversazione of the Northampton Institute, Clerkenwell, will be held to-morrow, December 6. The Marquis of Northampton will distribute the prizes.

MR. HERBERT J. FLEURE, a student of Prof. Ainsworth Davis at University College, Aberystwyth, has been elected a Fellow of the University of Wales. The Fellowship is one of the highest distinctions of the University, and its conferment for the first time upon a student who has been engaged in zoological research is of noteworthy interest.

THE influence which the universities in Germany have had upon industrial progress was emphasised by Prof. Senier in an address entitled "Bonn on the Rhine: Pages from its History and Stray Thoughts on Education" (Dublin: Edward Ponsonby), recently delivered at Queen's College, Galway. It is sometimes thought that the advance of German industry has been due to technical schools, but Prof. Senier remarks: "Probably it would be more correct to say that the technical schools are due to the rise of industries. No doubt technical schools have had and will have some effect in assisting manufactures. But the main source of those industries depending upon science has always been and must always be science itself, the outcome of university work." In this opinion Prof. Senier follows what the readers of NATURE have been familiar with during the last twenty years.

A GIFT of 5000*l*. has been offered to the University of St. Andrews by Dr. T. Purdie, professor of chemistry in the University, for the purpose of building and equipping a small chemical research department. In his letter to Principal Donaldson intimating the gift, Prof. Purdie says that their universities are very poorly provided for research when compared with those of foreign countries, and that scientific industries suffer in consequence. At St. Andrews in particular, except in zoology, there is no special provision in any of the science departments for original investigation. He therefore trusts that the University Court will accept his gift for the purpose mentioned, and that means may soon be found to equip other science departments. The success of the scheme, however, presupposes that scholarships will be available to encourage students to undertake post-graduate work, and also that an annual grant of money will be provided for laboratory expenses. He makes it a condition of his gift that the Carnegie trustees shall regard the scheme with favour and signify their willingness to help in the direction indicated. The gift is made in memory of his late uncle, Mr. Thomas Purdie, of Castlecliffe.

SO many subjects are dealt with in the latest report of the U.S. Commissioner of Education that it is impossible to do more than mention a few matters considered in this volume, the contents of which occupy as many as 1280 pages. An account is given of the origin, growth, influence and relation to the public of the great secondary schools of England. The change in the character of secondary instruction in some schools from the old exclusively classical system to one related to modern requirements is pointed out in connection with its cause—the demands of commerce and industry. The national conservatism appears in the slow rate of change and the spirit in which science is even now accepted in the secondary school

curriculum. A detailed table of the schools of Berlin is given in the report, and it shows a surprising variety of educational agencies in the German capital. The table reveals the fact that Berlin has 103 secondary schools and 306 elementary schools. It is evident from the table that the city is making great efforts to assist the industrial education of its youth. Another article in the report contains a statement of the number of students in higher institutions of learning in fifteen prominent countries. The tables show, first, that the Teutonic nations—Germany, Austria, Switzerland, Belgium and the Netherlands—are in the front rank, not only in the number of students in higher institutions, but also in the ratio of increase. Second, that the percentage of increase in students of technical institutions, such as polytechnic institutions, agricultural and mining schools, is everywhere larger during the year 1898-99 than in those of universities and colleges. We note, for instance, that the attendance in universities in Germany increased 6·5 per cent., but that of technical institutions increased 8·2 per cent. In Austria the increase in universities was 4 per cent.; in technical institutions it was 7·8 per cent. In Russia the increase in universities was 1·2 per cent.; in technical institutions it was 7·7 per cent. Such figures are significant, inasmuch as they indicate that the industries of Europe and America are claiming more thorough and more special preparation than formerly.

SCIENTIFIC SERIAL.

Transactions of the American Mathematical Society, vol. ii. No. 4, October.—Geometry of a simultaneous system of two linear homogeneous differential equations of the second order, by E. J. Wilczynski, is a continuation of a previous paper (in No. 1 of the present volume), entitled "Invariants of Systems of Linear Differential Equations." In this some new theorems are deduced, but it is mainly concerned with geometrical interpretations. The author confines himself to the special case of the equations

$$y'' + p_{11}y' + p_{12}z' + q_{11}y + q_{12}z = 0,$$
$$z'' + p_{21}y' + p_{22}z' + q_{21}y + q_{22}z = 0,$$

the independent variable being x. The consideration of configurations in hyperspace is avoided. The treatment is connected with the work of Halphen and Fano upon the single linear differential equation (*cf. Math. Annal.* vol. liii.).—The chief result of Dr. L. E. Dickson's theory of linear groups in an arbitrary field is the exhibition of four infinite systems of groups of transformations which are simple groups in every domain of rationality. For the case of the field of all complex numbers these groups are the simple continuous groups of Lie. The chief results in a finite field are given in the author's "Linear Groups" (Teubner, Leipzig, 1901). Corresponding to the isolated group of 14 parameters, there exists in the Galois field of order p^n a new system of simple groups of order $p^{6n}(p^{6n}-1)(p^{2n}-1)$.—On certain aggregates of determinant minors, by W. H. Metzler. In 1888 Dr. T. Muir showed (*Proc.* Roy. Soc. Edin., pp. 99–105) that a linear rotation exists between certain minors of a centro-symmetric determinant similar to Kronecker's relation between the minors of an axi-symmetric determinant; and in 1900 he gave two theorems connecting the minors of any determinant, the first of which reduces to Kronecker's relation and the second of which reduces to his 1888 relation.—Prof. Metzler extends these relations and gives a series of types of linear relations between the minors of a centro-symmetric determinant. The present memoir gives the number of relations of each type.—Two papers by A. Pringsheim are (1) ueber die anwendung der Cauchy'schen multiplications regel auf bedingt convergente oder divergente reihen, and (2) ueber den Goursat'schen beweis des Cauchy'schen integralsatzes. These, as well as several of the other papers in the number before us, were communicated to the Ithaca meeting of the Society (August 19).—New proof of a theorem of Osgood's in the calculus of variations, by Oskar Bolza, is a simple one of the important characteristic property of a strong minimum in the calculus.—On certain pairs of transcendental functions whose roots separate each other, by the same author, proves the theorem, if, in a certain interval, p, q, ϕ_2, ϕ_1, ψ_2, ψ, are continuous real functions of the real variable x, and if the last four of these functions have continuous derivatives, then, y being a solution not identically zero of the differential equation $y'' + py' + qy = 0$, the roots of the functions $\phi_2y' - \phi_1y$, $\psi_2y' - \psi_1y$ will separate each other if no one of the three functions $\phi_1\psi_2 - \phi_2\psi_1$, $\phi_1'\phi_2 - \phi_1\phi_2' + \phi_1^2 + p\phi_2\phi_1 + q\phi_2^2$, $\psi_1'\psi_2 - \psi_1\psi_2' + \psi_1^2 + p\psi_2\psi_1 + q\psi_2^2$ vanishes at any point of the interval in question. Certain extensions of the above theorem are also established.—On the system of a binary cubic and quadratic and the reduction of hyperelliptic integrals of genus two to elliptic integrals by a transformation of the fourth order, by J. H. Macdonald, effects the reduction by a special involution of order four containing a form which is the square of a quadratic. Reference is made to Prof. Bolza's inaugural dissertation (Göttingen, 1886). The sections discuss theorems on the biquadratic involution having a complete square, the system of a cubic and two linear forms and their conjugate system, the system of a cubic and quadratic and their conjugate system, certain involutions, and miscellaneous results on biquadratic involutions containing a complete square.—On the theory of improper definite integrals, by E. H. Moore. In the paper the author discusses the types connected with the names of Cauchy, Riemann, du Bois-Reymond, Dini, Schoenflies, Harnack and Jordan, Hölder, and de la Vallée-Poussin. Prof. Moore himself defines a system of types, which differ according to the way in which the integral depends (by definition) upon the sets of points of singularity of the integrand function with respect to definite integration.—On the convergence and character of the continued fraction $\frac{a_1z}{1} + \frac{a_2z}{1} + \frac{a_3z}{1} + \ldots$, by E. B. Van Vleck, is a portion of the paper, contributed by the author to the August meeting of the Society, on the convergence of the continued fraction of Gauss. In this portion the theorem established is—if, in such a fraction, the greatest modulus of any point of condensation of the sequence a_1, a_2, a_3, ... is k, then within a circle of radius $1/4k$, described about the origin as centre, the continued fraction will represent an analytic function, and the only singularities of the function contained within the circle will be poles. In any region excluding these poles and lying in the interior of the circle the convergence will be uniform.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 21.—"The Pear-shaped Figure of Equilibrium of a Rotating Mass of Liquid." By Prof. G. H. Darwin, F.R.S.

"Sur la Stabilité de l'Équilibre des Figures Pyriformes affectées par une Masse Fluide en Rotation." By H. Poincaré, For. Mem. R.S.

"On the Process of Hair Turning White." By E. Metchnikoff, For. Mem. R.S.

Although the fact of hair turning white is a most familiar one, its mechanism has not as yet been unveiled. The authors of works on hair and dermatology acknowledge their ignorance concerning this subject.

Having undertaken a study on atrophic processes, and especially on senile atrophy, my attention has been called to the atrophy of hair pigment so frequent in old people.

Observations on grey hair, or on hair beginning to turn grey, showed me that the atrophy of its pigment is due to the intervention of phagocytes of the hair.

These cells have a single nucleus and their very different aspect one from another is due to numerous amœboid prolongations of their protoplasm. They are derived from the medullary part of the hair and make their way out into its cortical layer, where they absorb the pigment granules, which they then remove from the hair.

If we consider hair, one part of which is already white and the other still pigmented, we find a great many of these phagocytes. They are supplied with greatly developed prolongations and become insinuated between the keratic cells of the peripheral layer.

In absolutely white hair the phagocytes filled with pigment become more and more scarce, and most frequently completely disappear.

It is thus indubitable that the phagocytes of the hairs swallow up the granular pigment of the cortical layer and transfer it elsewhere, the result being the complete whitening of such hair. On observing the root of hair beginning to whiten, we often find a great many phagocytes filled with pigment.

The whitening of the hair of old dogs proceeds by the same mechanism. We equally find here a great number of phagocytes

supplied with numerous prolongations and stuffed with pigment granules.

The part played by phagocytes in the whitening of hair explains many phenomena observed long ago, but not as yet sufficiently understood. Thus, hair turning white in a single night, or in a few days, may be explained by the increased activity of hair phagocytes thus enabled to transfer the pigment in so short a time.

The mechanism of the whitening of hair through the agency of phagocytes allows this case of atrophy to be classed under the general laws of atrophy of solid parts of the organism.

"On the Inheritance of the Mental Characters in Man." By Karl Pearson, F.R.S.

(1) Mr. Francis Galton, in his "Natural Inheritance," first, I believe, endeavoured to give a *quantitative* appreciation of the inheritance of the mental characters in man. Mr. Galton's data were not very copious, and in default of a method of dealing quantitatively with characters not capable of exact scaling, it was not possible to deduce absolutely conclusive results. On November 19, 1899, a paper was read to the Royal Society showing how the inheritance of characters not capable of exact quantitative measurement might be deduced. I purpose in this notice to give only a few results from some very elaborate observations which have been made in the course of the last few years and reduced by the processes of that paper.

(2) The material was collected in two separate ways. In the first series—the Family Measurement Series—only physical characters were observed. This series was started six years ago, and upwards of 1100 families, father, mother, and not more than two sons and two daughters, were measured. The series was closed two years ago, and last year Dr. Alice Lee completed the reduction of this very large mass of material.

My second series is still more extensive; but it relates only to collateral—fraternal—heredity. It aims at observing a wide range of both physical and mental characters in pairs of school children. I have received most kindly aid from a great number of masters and mistresses in public schools, high schools, secondary and primary schools of all classes. This will be very fully acknowledged in the final publication of the results. But although the work has been in progress for three years, we have still only material enough to draw conclusions in the case of pairs of brothers, of whom more than 1000 cases have been observed.

(3) Only three of the physical measurements of this extensive series have yet been reduced, and the sister-sister and sister-brother observations will have to be carried on for another year or two before they are sufficiently numerous to be dealt with. The whole material will then require two or three years for tabulation and calculation. But as the problem of the inheritance of the mental characters and their correlation with the physical was occupying our attention in another field, the indefatigable Dr. Lee undertook the tabulation and calculation of the coefficients of heredity in the case of seven mental and three physical characters for pairs of brothers. The number of pairs dealt with in each case was 800 to 1000. The method adopted was that of the memoir on "The Inheritance of Characters not capable of Exact Quantitative Measurement."[1] Thus, under the heading *Conscientiousness* were two divisions, Keen and Dull, and the teacher might place a cross on either of these or on the dividing line. Similar divisions occurred in the other categories, except that *Intelligence* was given six and *Temper* three subdivisions, &c. The sole object in the present preliminary notice is to draw attention to the following results:—

Coefficients of Collateral Heredity.

Correlation of Pairs of Brothers.

Physical Characters. (Family Measurements.)		*Mental Characters.* (School Observations.)	
Stature	0·5107	Intelligence	0·4559
Forearm	0·4912	Vivacity	0·4702
Span	0·5494	Conscientiousness	0·5929
Eye-colour	0·5169	Popularity	0·5044
(School Observations.)		Temper	0·5068
Cephalic index	0·4861	Self-consciousness	0·5915
Hair-colour	0·5452	Shyness	0·5281
Health	0·5203		
Mean	0·5171	Mean	0·5214

The physical characters were measured or observed on two entirely different groups of individuals—in the one case adults, in the other children were examined. The means for both series are almost identical (·5170 and ·5172). Dealing with the means for physical and mental characters their likeness forces us to the perfectly definite conclusion: *That the mental characters in man are inherited in precisely the same manner as the physical.* Our mental and moral nature is, quite as much as our physical nature, the outcome of hereditary factors.

[1] *Phil. Trans.* A vol. cxcv. pp. 79–150.

Entomological Society, November 6.—The Rev. Canon Fowler, president, in the chair.—The Rev. F. D. Morice exhibited two imperfectly developed females of *Osmia leucomelana* found dead in a *rubus* stem at Woking with their cases.—Mr. C. P. Pickett exhibited a series of aberrations of *Colias hyale* taken at Folkestone during August 1900–1.—Mr. F. B. Jennings exhibited a specimen of *Trachyphloeus myrmecophilus*, Seidl., taken at Hastings in September last, retaining intact the deciduous "false mandibles," with the aid of which the imago of the species of this and certain other genera of weevils is said to work its way to the surface after emerging from the pupa underground. These mandibles are usually shed as soon as the imago begins its life above ground, as there is no further use for them.—Mr. W. J. Kaye exhibited a collection of butterflies made by him in Trinidad, with several hitherto undescribed species. He said that the probable total rhopalocerous fauna was about 250 species, the island—about the size of Somersetshire—being thus remarkably rich in butterflies. The number of the species in the families exhibited were Nymphalidæ 34, Satyridæ 13, Papilionidæ 6, Pieridæ 31, Erycinidæ 29, Lycænidæ 27, Hesperiidæ 62—nearly all taken within three or four miles of Port of Spain. The series of *Heliconius telchinia* and *Tithorea megara*, var. *flavescens*, were particularly fine, showing the yellow coloration only found in Trinidad and the coast of Venezuela immediately opposite. A long series of *Papilio xeuxis*, and *Papilio alyattus*, many of them bred from the same parent ♀, show that these two are in reality identical species. The number of Erycinidæ in Trinidad compared with the poverty of the same species in other West Indian islands indicates the different origin of its fauna, and suggests affinity with the mainland of Venezuela, which at the nearest point is but seven miles distant.—Dr. Chapman exhibited specimens of *Parnassius apollo* taken last July in Castile and Aragon (Spain), as well as a number of specimens of both *P. apollo* and *P. delius*, chiefly Swiss and French, taken by himself, Mr. Tutt, Mr. A. H. Jones (at Digne), and Mr. Rowland-Brown (at Susa, N. Italy), for comparison with the Spanish specimens and to illustrate the extent to which the races of these species approach each other in western Europe.—Mr. G. C. Bignell sent for discussion a specimen of *Sphecophaga vesparum*, Curt., and the cocoon from which it had been bred.—Mr. Gilbert J. Arrow communicated a paper upon the genus Hyliota, with descriptions of new forms and a list of described species, and Mr. W. L. Distant, contributions to a knowledge of the Rhynchota.

Royal Meteorological Society, November 20.—Mr. W. H. Dines, president, in the chair.—A paper by Mr. A. Lawrence Rotch on the exploration of the atmosphere at sea by means of kites was read by the secretary. The author has for some years past devoted his attention to the use of kites to obtain meteorological observations at the Blue Hill Observatory, Mass., U.S.A., and he has successfully carried on the work of exploring the air there to a height of three miles by several hundred kite flights executed in varied weather conditions whenever the velocity of the wind exceeded twelve miles an hour. Certain types of weather, however, such as anti-cyclones, accompanied by light winds, can rarely be studied. Mr. Rotch now proposes the employment of kites carrying meteorographs on steamships, especially on vessels cruising in tropical oceans. He has himself demonstrated the practicability of this scheme, as on August 22 last he raised a kite to an elevation of half a mile from a tow-boat in Massachusetts Bay, when the velocity of the wind at sea-level varied between six and ten miles an hour. At the end of the same month, when crossing the North Atlantic from Boston to Liverpool on the steamship *Commonwealth*, he was able to raise kites carrying a meteorograph to an altitude of 1600 feet on five days out of the eight. The chief feature of these records was the rapid change of temperature with height.—A paper by Prof. J. Milne, F.R.S., on meteorological phenomena in relation to changes in the vertical, was also read by the secretary. When resident in Japan some years ago the author carried on numerous observations by seismographs for ascertaining changes in the vertical, and found that

the more important displacements of the horizontal pendulums are of three types, viz. intermediate, long and short period wanderings. During the last five years Prof. Milne has had continuous photographic records of a horizontal pendulum at his residence at Shide, Isle of Wight, and he now makes a comparison of these records with the weather conditions prevailing during the first six months of 1901. He says that assuming that a locality can be chosen where the diurnal wave and effects due to rain and desiccation are small, which his observations indicate as possible, records of what appear to be the effects due to barometrical gradients may be obtained. When these are large and appear suddenly, the movements of the pendulum may be marked. At Shide the westerly displacement of a pendulum has, for several years past, been regarded as indicating the approach of bad weather.

Anthropological Institute, November 12.—Mr. W. Gowland, vice-president, in the chair.—Mr. R. Shelford exhibited (1) a series of slides of natives of Sarawak, and (2) a collection of gold jewellery found in Borneo, lent by H.H. the Rajah of Sarawak.—Mr. Shelford read a paper entitled "A Provisional Classification of the Swords of the Natives of Sarawak."—Mr. J. Gray exhibited a craniometer for measuring the height of the head.

November 26.—Mr. C. H. Read, ex-president, in the chair.—Mr. E. Willett exhibited a number of Palæolithic implements from Savernake.—Mr. N. W. Thomas exhibited a collection of "totem-stones" collected by the Hon. Auberon Herbert. The exhibit was discussed by Mr. Balfour and Mr. Read.—Mr. R. F. Gatty read a paper on dwarf flints from the sand mounds of Scunthorpe, illustrated by a number of specimens.

MANCHESTER.

Literary and Philosophical Society, November 26.—Mr. Charles Bailey, president, in the chair.—Prof. H. B. Dixon mentioned that Mr. H. Brereton Baker had succeeded in making a mixture of hydrogen and oxygen so pure that it would not explode when the vessel containing it was raised to a red heat or when a silver wire was melted in it. In one case some water was gradually formed, so that the explosion of the gases would seem to depend on the presence of some impurity other than steam itself.—Prof. F. E. Weiss exhibited two dwarf Japanese trees which have been purchased for the Manchester Museum. They were *Pinus parvifolia* and *Thuja obtusa* (the Japanese cypress), both natives of Northern Japan, where they grow at very great altitudes and are naturally of small growth. The trees exhibited, which were thirty and forty years old respectively, were only six to nine inches in height, these dwarf forms being obtained by a system of starving and pruning back the plants and by contortions of the stem and branches which retard the nutritive processes.—Mr. J. E. Petavel read a paper entitled "On the Measurement of High Explosive Pressures." After a short review of the various methods and instruments used by Rumford, Bunsen and Rodman in the first half of the nineteenth century, and by Noble, Berthelot, Vieille, Le Chatelier and Mallard in recent years, the author went on to describe a new form of recording gauge, which is, in principle, not far removed from the ordinary crusher gauge. The short copper cylinder is replaced by a hollow steel cylinder one inch in diameter and five inches long, the relative cross-sectional areas of the piston and cylinder being calculated so that the strains are well below the elastic limit of the material. The actual motion of the piston is thus limited to one or two thousandths of an inch, and a very high time period is obtained. The motion of the piston is transmitted to a mirror, the movement of which is photographically recorded on a revolving drum. The amplitude of the records thus obtained is about 1″; they can be measured to an accuracy of about one-thousandth of an inch. A number of records referring to mixtures of coal gas and air or oxygen and hydrogen were shown, the pressures ranging up to twelve thousand pounds per square inch.

PARIS.

Academy of Sciences, November 25.—M. Fouqué in the chair.—On the absence of action of a magnetic field upon a mass of air which is the seat of a current of displacement, by M. R. Blondlot. It has been shown in a previous paper that if a mass of air is moved in a magnetic field normally to the lines of force no electric displacement results in this mass of air. From this it follows that a mass of air which is the seat of an electric displacement should undergo no action in a magnetic field. If the principle of action and reaction is applied to this proposition it leads to the conclusion that a current of displacement in the air exerts no magnetic action, and consequently that the charging current of a condenser is an open current from the magnetic point of view. This is in direct opposition to one of the fundamental principles of Maxwell's theory, and choice has to be made between renouncing this theory or the principle of action and reaction.—On ibogine, the active principle of a plant of the genus Tabernæmontana, coming from the Congo, by MM. A. Haller and Ed. Heckel. In the Congo and neighbouring countries several species of plants possessing analeptic and stimulating properties are used by the natives under the name of Iboga. These peculiar properties have been assigned by MM. Dybowski and Landrin to a special glucoside, by M. Schlagdenhaufen to a new alkaloid. The specimens of this plant shown in the Colonial Exhibition of 1900 have been utilised for the extraction of this substance. The amount of material was small, but it is clear that the substance is a true alkaloid and not a glucoside, and the formula $C_{26}H_{32}N_2O_2$ is provisionally assigned to it. The alkaloid itself has been obtained in the form of white crystals, but all the salts obtained up to the present are amorphous.—The mummified birds of ancient Egypt, by MM. Lortet and Gaillard. The specimens examined differ greatly in their states of preservation, some being so perfectly preserved that a simple examination of the feathers was sufficient for the identification whilst in others the skeleton was the only possible guide. Some thirty-eight species were identified, the greater number of these not having been found before in the mummy state.—The *Okapia Johnstoni*, a new mammal allied to the giraffe discovered in Central Africa, by Prof. E. Ray Lankester. A drawing and description of a new mammal discovered by Sir H. Johnstone in the Semliki Forest on the borders of the Congo Free State and Uganda. The skin bears no resemblance to that of the giraffe, but its relationship to this animal is absolutely demonstrated by its skull. It may possibly be the living representative of the Miocene genus Helladotherium.—Remarks by M. Albert Gaudry on the preceding paper. M. Gaudry presented at the same time a restored head of Helladotherium.—M. Yves Delage was elected a member in the section of anatomy and zoology in the place of the late M. de Lacaze-Duthiers; M. Gouy, a member in the section of physics in the place of the late M. Raoult.—On the number of roots common to several equations, by M. A. Davidoglou.—The determination of some coefficients of self-induction, by Mr. G. A. Hemsalech. In a previous paper on the spectra of electric sparks the coefficients of self-induction were calculated from the dimensions of the coils. It has now been recognised that these were too great, and hence they have been redetermined experimentally. The most advantageous values for spark-spectrum observations are now given as ·00286 Henry for cobalt, zinc, magnesium and aluminium; ·00689 Henry for manganese aad silver; ·0254 Henry for antimony; and ·0419 Henry for iron, nickel, cadmium, tin, lead, bismuth and copper.—On the regular distribution of the magnetic inclination and declination in France up to January 1, 1896, by M. E. Mathias.—On the application of the clear chamber of Govi to the construction of a comparator for end standards, by M. A. Lafay. The arrangement described allows the difference in length between a standard and its copy to be expressed as the algebraic sum of the displacements of two plane mirrors mounted on micrometer screws. It has the advantage over the ordinary methods in avoiding all deformations due to the actual contacts of the ends of the standards with the holders used in the ordinary instruments.—On the combinations of aluminium chloride with the alkaline chlorides, by M. E. Baud. It is shown by thermochemical studies that the compounds $Al_2Cl_6.3NaCl$ and $Al_2Cl_6.3KCl$ exist, and very probably also $Al_2Cl_6.6NaCl$ and $Al_2Cl_6.6KCl$.—On the preparation of barium, by M. Guntz (see p. 112).—On a new volatile salt of beryllium, by MM. G. Urbain and H. Lacombe. A description of the preparation and properties of a basic acetate of beryllium. It boils under the ordinary pressure without any sign of decomposition at a temperature of 330–331° C., and its vapour density at the temperature of boiling mercury was found to be 13°·9, which is in accordance with the atomic weight Be = 9.—The action of fuming sulphuric acid upon acetaldehyde and propaldehyde and acetone, by M. Marcel Delépine.—On the electrolytic preparation of the halogen derivatives of acetone, by M. A. Richard. The electrolysis of mixtures of acetone with hydrochloric and hydrobromic acids gives monochloroacetone and monobromo-

acetone respectively. In the present paper the conditions necessary for a maximum yield of the halogen derivative are determined.—On the transformation by a new reaction of two xanthydrols into xanthenes, by M. R. Fosse.—The etherification of phosphorous acid by glycerol and glycol, by M. P. Carré.—On the reserve store of carbohydrates in the seed of *Aucuba japonica*, by M. G. Champenois. The seed of this plant contains a large quantity of cane-sugar accompanied by a glucoside. Besides the soluble compounds the seed contains as constituents of its hard albumen a galactane, a mannane and a pentane which give on hydrolysis galactose, mannose and a pentose which appears to be arabinose.—On an experiment of M. Berthelot relating to the transformation of glycerol into sugar by the testicular tissue, by M. Gabriel Bertrand. It is found that the action of the sorbose bacterium upon glycerol, which up to the present has been regarded as specific, is really an action common to different organisms.—Experiments on chlorophyll assimilation, by M. M. Harroy. The author has repeated the experiments of M. Friedel, but has not been able to confirm them, and he regards it as premature to state as a fact that the chlorophyllian synthesis may take place outside the vegetable organism and without the intervention of living matter.—Researches on the law of action of sucrase, by M. Victor Henri. The speed of inversion of saccharose by any acid is at any instant proportional to the quantity of saccharose present in the solution, from which is derived the well-known formula giving the relation between the time and the quantity present $k = 1/t \log a/a - x$. It is found that the inversion of sugar by sucrase takes place more rapidly than corresponds to this law, and a new formula is derived which expresses the experimental results better: $2k_1 = 1/t \log a + x/a - x$.—The cell of Sertoli and the formation of spermatozoids in the sparrow, by M. Gustave Loisel.—Some new geological observations in the Belledonne chain, by M. Pierre Termier.—A graphical method permitting the study of the circumstances of the course of a steerable aërostat, by the examination of the projection of its trajectory upon the earth, by M. J. Armengaud, jun.—The increase of the number of red corpuscles in the blood during a balloon ascent, by M. J. Gaule. It is shown that there is a true formation of red globules on arriving suddenly at a high altitude, the phenomena taking place with great rapidity.—The scientific treatment of deafness, by M. Marage.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 5.

ROYAL SOCIETY, at 4.30.—On the Spontaneous Ionisation of Gases: C. T. R. Wilson, F.R.S.—In title only: Notes on Quantitative Spectra of Beryllium: Prof. W. N. Hartley, F.R.S.—Notes on the Development of *Paludina vivipara*, with Special Reference to the Urinogenital Organs and Theories of Gasteropod Torsion. (Preliminary Note): Miss I. M. Drummond.—In title only: Preliminary Account of the Prothallium of *Phylloglossum*: Prof. A. P. W. Thomas.

THE BACTERIAL PURIFICATION OF SEWAGE.

Sewage and the Bacterial Purification of Sewage. By Dr. S. Rideal. Pp. iii + 308. (London: Sanitary Publishing Co., 1901.) Price 14*s.* net.

THE practicability of effecting the purification of town sewage on the large scale by bacterial agency has now been abundantly proved. The process has passed beyond the experimental stage, and must now be acknowledged as the only method which can convert the putrescible matter of sewage on the large scale into inoffensive and harmless substances. Accordingly all trustworthy information respecting the results which have been arrived at from the lengthy experimental trials, and from the application of these results on the large scale, will be welcome to public sanitary authorities, and perhaps even still more acceptable to the professional advisers of these bodies. The treatise under review has been written by one who has carefully watched the progress, and who has had a long and varied experience, of bacterial treatment. The book is, therefore, undoubtedly worthy of careful perusal and consideration by those who are responsible for disposing of the sewage from houses, villages or towns.

The author covers a wide ground. He treats of the general character of sewage, and gives an historical sketch of the processes which have been resorted to for disposing of it. He also enters fully into the modern methods which have been recommended for the chemical examination of sewage and of sewage effluents, and states the standards of purity which have been suggested. Probably his description of the methods of collecting and examining these liquids will be of special value, since no such general description seems to be at present available. The summary of Dr. Houston's work on the identification of the bacteria present in raw sewage, a detailed account of which has appeared in the reports published by the London County Council, will also be useful, together with the account of the most important chemical changes which are brought about by bacteria. Naturally, also, some account is given of the treatment of sewage by irrigation and by chemicals, and of the "sterilisation" processes—processes which appear in the light of present knowledge of doubtful advantage, since they destroy the vast number of bacteria which effect or complete the purification of sewage, in order to make sure that a small minority of possibly injurious bacteria are disposed of.

The latter portion of the book will undoubtedly command most general attention, since here the author deals with bacterial purification. This is treated of in some detail, and the information which is given has been collected from the most trustworthy sources generally available. One can only regret that the large amount of useful matter accumulated has not been somewhat more systematically arranged and carefully summarised and compared; and, above all, that the author has not stated very clearly and emphatically the conclusions which he himself has arrived at from its careful consideration. The author has, however, apparently not been willing generally to act as assessor of the relative value of the different bacterial methods and apparatus, and due acknowledgment should be made of the time and trouble which he has expended in bringing together important information much of which, until now, has existed only in the form of scattered reports and papers. That the work which he has done in this direction is really valued is shown by the fact that a second edition of the book has been issued twelve months after the original publication; and it may be stated that the author has, as far as possible, availed himself of the opportunity which a new edition afforded him of bringing the matter up to date.

The author speaks in his preface "of the experiments on bacterial purification, which have now been carried out on a sufficiently large scale to establish the safety of embarking on the treatment of sewage on bacterial lines for even the largest centres of population." This statement proves that he is in touch with the recent experimental trials of the method at the sewage outfalls of our great towns. And it cannot be too emphatically stated that the near future is to see the adoption on the large as well as the small scale of this most rational process of "self-purification" of sewage. For after all bacterial purification is natural purification. It simply amounts to allowing the living agents of purification, which are present in the raw sewage in immense numbers, to carry out their useful function under the most favourable conditions. This adoption of natural methods must surely commend itself; and no one who looks at sewage treatment from a disinterested point of view will regret the approaching general relinquishment of artificial chemical or electrical treatment in favour of allowing natural agencies to have free course, provided only that reasonable efficiency and economy can be assured in making the change. This natural treatment may in some localities be effected on sewage farms by the development of bacteria in a suitable soil; but in most localities great advantage is obtained by substituting for the soil properly constructed bacteria beds, in which the treatment can be carried out on a smaller area and under more complete control than by means of the bacteria in the soil.

The experience and knowledge derived from several years' natural purification of sewage on the small scale in coke bacteria beds at the London and Manchester outfalls should suffice to give satisfactory assurance in these respects. After varied and continued trials it has been found independently at both these important centres that the raw sewage on its arrival at the outfalls should be roughly screened and then subjected to sedimentation without previous admixture with any chemicals. It has been shown that sedimentation may be appropriately allowed to take place in open tanks or channels in two stages. Much sand, road detritus and cellulose matter can thus be first removed, and this may be simply thrown out upon the land or dealt with in destructors without causing offence; while in the second sedimentation "sludge" consisting of fæcal and putrescible matter subsides. If the substances which are separated out by the latter sedimentation are simply left in contact with the sewage, which constantly flows over them, at least 40 per cent. of the solid sediment disappears

by bacterial action. Accordingly by the double sedimentation an average of more than 60 per cent. of the suspended solid matter or "sludge," which was present in the raw screened sewage, has been caused to disappear. This implies a very considerable diminution of cost in sludge removal and disposal; but it secures the further advantage that the still impure liquid flowing from the settling tanks has become admirably adapted for undergoing adequate purification in the bacterial coke-beds. It is noteworthy that the full power of disposing of sludge is only developed in the sludge after it has remained in contact with the flowing sewage for some considerable length of time; and it is only stale sludge which is efficient in resolving the solid insoluble matter into soluble and gaseous forms. This delay is due to the necessity of cultivating in the sludge the necessary species of bacteria, which are derived from the sewage itself.

The most efficient and rapid method of dealing with the impure liquid, which flows from the settling or so-called "septic" tanks, has been found to consist in treating it intermittently in coke-beds, which have been primed with bacteria by being placed for some weeks frequently in contact with sewage. The complete cycle of treatment in the London beds consists in filling the coke-bed, emptying it after a couple of hours, and then leaving its coke contents in contact with the interstitial air for another period of two hours. It has been found possible to repeat this cycle four times in twenty-four hours, and using beds six feet in depth to purify the settled sewage at the rate of two million gallons per acre per twenty-four hours. By this purification an effluent is obtained which is saturated with dissolved oxygen, which remains entirely inoffensive in smell for an indefinite period in an incubator at summer heat, and which, therefore, when discharged into a water-course would maintain the respiration of fish and would never render the water offensive.

Chemical examination shows that the treatment in the coke-bed has reduced the readily oxidisable dissolved matter in the settled sewage by from 60 to 70 per cent., and the whole oxidisable matter in the unsettled raw sewage by more than 90 per cent.

Bacteriological examination indicates that the effluent contains large numbers of bacteria; but the presence of these bacteria is useful in effecting inoffensively the removal of the organic substances, which still remain in the effluent, as soon as the effluent mingles with the well-aërated river water.

It is noteworthy that the sewage capacity of a newly-made coke-bed progressively decreases for a time, while its purifying power is being developed by contact with settled sewage. But the capacity ultimately becomes equal to about 30 per cent. of the whole cubic space which has been charged with coke; and, if the treatment is carried out regularly under proper supervision, this capacity fluctuates by only a few units per cent. above and below this final capacity throughout the period of many years during which the bed has as yet been worked.

The decrease of capacity to 30 per cent. is the so-called "choking" of the bed. It is due to a bacterial jelly-like growth of bacteria and zooglœa upon the coke-surfaces. If this jelly is removed and exposed to air over mercury, it will rapidly absorb oxygen from the air, and will therefore produce a partial vacuum. It appears that this growth is actually charged with oxygen during the aëration or resting of the coke-beds between the chargings with sewage liquid. The growth upon the coke-surfaces, which reduces the capacity of the bed, appears, therefore, to be the essential element of successful purification.

It is noteworthy that the growth may be unduly developed, with corresponding decrease in the sewage capacity of the bed, by over-frequently filling the bed; and by resting the bed, or reducing the number of fillings, the growth may be diminished and the capacity of the bed correspondingly increased. A great increase in the development of the jelly involves increased purification, but reduction in the amount of sewage dealt with, and *vice versâ*. Accordingly a working rate which is most advantageous on all grounds must be arrived at by trial and experience.

Careful examination of the composition of the interstitial air, even at the bottom of a coke-bed thirteen feet in depth, proves that the air is not deficient in oxygen to an extent greater than 25 per cent. of that normally present in fresh air. It appears, therefore, that although oxygen is being rapidly absorbed during the resting or aëration of the bed, the oxygen which is absorbed is rapidly replaced by natural diffusion, and mechanical aëration of the bed is unnecessary.

It has been proved that the chemical refuse which is found in the sewage of manufacturing towns seldom exerts any prejudicial action on the action of the bacteria or upon the coke-beds. In some towns, however, a preliminary treatment of the sewage has been adopted in order to remove special chemical refuse when it is present in very large quantity. This is not the case either in London or in Manchester.

One hears occasionally of so-called failures in securing bacterial purification of sewage. It is not too much to say that such failures have been due to the improper construction or working of the bacteria beds. Apparently we have still to learn of want of success when an intelligent attempt has been made under competent and experienced direction.

Although the process of natural purification of sewage must eventually become general, its adoption will undoubtedly be delayed by the lack of knowledge on the part of the majority of our public bodies and even on the part of some of their advisers. Those who wish to see the satisfactory results of experimental inquiry usefully and advantageously applied on the large scale will accordingly welcome the appearance and success of such treatises as the one which has suggested the present review.

FRANK CLOWES.

FIFTY YEARS OF BIOLOGICAL STUDY IN AUSTRIA.

Botanik und Zoologie in Oesterreich in den Jahren 1850 *bis* 1900. *Festschrift v.d.K.K. Zoologisch-Botanischen Gesellschaft in Wien.* Pp. x+620; with 38 plates and 9 cuts. (Vienna: Alfred Holder, 1901.)

THIS magnificent work illustrates in every way the jubilee of the K.K. Zoological and Botánical Society of Vienna. Twenty-two authors have collabor-

ated in its production; and its contents are as follows:—(A) A short preliminary history of the Society. (B) A descriptive history of the institutes and corporations dealing with zoology and botany, including horticulture and agriculture. (C) A history of botany in Austria during the fifty years, under the three headings of (*a*) phytogeography; (*b*) morphology, ontogeny, and systematics of cryptogams; (*c*) morphology, ontogeny, and systematics of phanerogams; (*d*) anatomy and physiology of plants.

(D) A history of zoology in Austria during the last half-century: (1) morphology and systematics, including bionomics and zoogeography; this enormous range is treated in monographs of unequal compass—Protozoa, Cœlenterata, Echinoderms and Worms are the subject of one, Tunicates and Molluscs of another, Molluscoids of a third, while the classes of Vertebrata and Arthropods, and the orders of insects among the latter, receive distinct consideration; (2) a separate article deals with animal morphology and physiology.

A bibliography of the introductory discourses ("Wrogrammaufsätze") of the educational establishments closes the text. The plates are all well-executed lithographs of (deceased) workers at our sciences, and the cuts are for the most part full-page illustrations of biological institutions. Separate indexes of singular completeness are appended, and greatly enhance the value of the book as a work of reference. Unfortunately, in the nominal index no special reference is given to the pages on which the short biographical sketches are to be found, which, as in the case of Claus and Wiesner, for example, may rise to the dignity of scientific biographies.

Thus the work contains a singularly complete record of the work done in natural history in the Empire-Kingdom practically since its inception in the forties of the late century; for previous to 1845 there existed only agricultural, horticultural and medical societies, which dealt incidentally with nature study. In that year a union of "Freunde der Naturwissenschaften" was founded in Vienna. A year later was the Vienna Academy of the Sciences founded, by the exertions of Prince Metternich, a name associated in other domains with reactionary obscurantism. The modest union formed by Haidinger, which met in the Botanic Gardens, worked quietly on, independently, through the troublous times of '48–'50; but in 1850 the primary intention of converting the occasional publication of *Mittheilungen* into a regular *Zeitschrift* developed into the formation of a Zoological and Botanical Society, leaving the geological sciences to the Reichsanstalt. George Frauenfeld, the zoologist, was the founder of the movement, and the first secretary of the Society, which attracted all workers at the study of organisms living and extinct. As in England at that time the biological sciences were largely cultivated by amateurs of the highest birth and rank, so did the young Austrian society gain aristocratic support from the beginning. The first president was Prince Richard zu Khevenhüller Metzch, the second Prince Colloredo Mannsfeld, and we read of the latter that "few were the board meetings from which his Serene Highness was absent." In a country where one-half the population is illiterate, we can understand that education in the highest sense must assume an aristocratic tinge, and the noble particle "von" recurs frequently among the workers whose names are cited. This much we gather from the short history of the Society, related by Dr. Brunner v. Wattenwyl.

In the histories of botany and zoology, those of phytogeography and zoogeography hold the first places. One of the first objects set before the Vienna society at its foundation was the study of the native organisms of the Fatherland, and many of the provincial bodies have devoted their chief energies to this pursuit. When the faunistic and floristic studies of Austrian travellers are added, we can but admire the wonderful and successful work of a country usually held to be rather behind the average advancement of Europe.

But to say this gives no adequate account of the activity of Austrian biologists. In botany, over against such systematists as Endlicher, Fenzl and Engler may be set Unger, the discoverer of cilia in the lower plants; Ingen Housz, one of the fathers of plant physiology; Wiesner and Leitzeb, the histologists and physiologists; Kerner v. Marilaun, whose grasp of plant-bionomics was of the strongest and widest; and Čelakowsky, with his unrivalled knowledge of the morphology of flowering plants and their "monstrosities."

When we turn to the history of zoology we find a similar catholic productivity. Unfortunately, the matter is much more scattered, as we have seen in our survey of the contents of the book. Austrian zoologists, indeed, occupy a commanding position: we need but note C. Claus, systematist and morphologist, whose epoch-making works on the Crustacea and brilliant studies on the Cœlenterates were perhaps second in importance to his stimulating powers as an exponent and teacher; and v. Stein, who practically laid the foundations of our knowledge of the Flagellates. But in every section of zoology Austrians have distinguished themselves, and one of them, F. Eilhard Schulze, is the professor at Berlin.

If we ask ourselves the causes of the extraordinary scientific fertility of a union of countries numbering in all fewer inhabitants than Great Britain, and half of them illiterate for the greater part of the last half-century, the first that presents itself is probably provincial patriotism: each country is anxious that its own possessions shall be duly recognised; and no one can doubt the efficiency of such a stimulus to the capable student of nature. But the desire is useless without the power to accomplish. We can only find this in the encouragement given to children in Central Europe in the study of systematic and descriptive natural history, and especially that of the local flora. This teaches system, careful observation, accurate detailed description and record—a combination of acquirements realised in none of the disciplines in our own school use. Such work may commend itself as essentially "heuristic" to our enthusiastic band of reformers of school programmes. Moreover, it *does not* involve the direct teaching of philosophical ideas, but recently acquired by the pioneers of science and unintelligible to the young mind, which is, on the other hand, trained not to shirk the irksome accumulation of facts: indeed, the results will depend largely on the work of the scholar himself, and not on his passive reception of the teacher's ideas.

Hæckel has, we know, spoken disparagingly enough of mere systematism, and compared it to "postagestampology" (the word "philately" had not then been invented). But we read in the dedication of the "Generelle Morphologie" to Gegenbauer how, as a boy of twelve, he had collected a herbarium of local plants with a set of intermediate forms between the "critical species," and already had been led thereby to doubt the orthodox view of the constancy of species; we know his masterly unravelling and grouping of the appalling wealth of forms in the Radiolaria. De Bary once said to the writer: "Without a good systematic knowledge to begin with, no botanist can tell where he is, nor what he is dealing with." Charles Darwin began as a collector, and monographed the Cirrhipedia, and Alfred Russel Wallace was a collecting naturalist. If we want to place ourselves on a par with Austrian and German biologists we must reform our teaching of botany on the common-sense lines followed so successfully abroad, and once introduced by Henslow into the primary teaching of his village school in East-Anglia. As a preliminary to the morphology and bionomics of our academic programmes, there must be laid a sound foundation in the knowledge of organic external form and variety. And so the scientific training of the individual will be pursued on lines corresponding to the acquirement of scientific knowledge by the race, a course which should, at least in this case, commend itself to all educational reformers. M. H.

GEOGRAPHICAL DISCOVERY.

L'Epoca delle grandi Scoperte geografiche. Di Carlo Errera. Con 21 carte, &c. Pp. xvi + 432 (text, 357). (Milano: Hoepli, 1901.) Price L.6.50.

THIS useful, brightly-written and well-illustrated summary of the geographical progress of Christendom, from the beginning of the Middle Ages, is divided into twelve parts, of which the first eight deal with the pre-Columbian time and the last four with the great age of discovery, from Columbus to Magellan. Among the twenty illustrations are four reproductions of early mediæval maps, from Miller and Beazley, one of Carignano's Portolano of 1300, one of Fra Mauro's map of 1459, one of a section of Juan de la Cosa's chart of 1500, one of the Strassburg Ptolemy of 1513, and one of the 1529 mappe-monde of Diego Ribero. Most of the latter are reproduced from Ruge's "Geschichte des Zeitalters der Entdeckungen." In its text the present work is also mainly based, for its later chapters, upon the same and other works of Ruge's, as well as upon Kretschmer's "Entdeckung Amerikas," Nordenskjöld's "Facsimile Atlas," Harrisse's "Christophe Colomb" and other studies, and Günther's "Zeitalter der Entdeckungen"; for its earlier upon Nordenskjöld's "Periplus," Hughes' "Storia della Geografia," Heyd's "Commerce du Levant," Uzielli and Amat's "Studi biografici . . . sulla Storia della Geografia," K. Miller's "Mappæmundi," Beazley's "Dawn of Modern Geography," Avezac's edition of, and introduction to, Carpini, Yule's Marco Polo, &c.

But although essentially a compilation from more extensive and specialised studies on the history of exploration, Prof. Errera's contribution to the "Collezione Storica Villari" has great merits. It describes with excellent lucidity, compression, and good sense the chief epochs in the great drama of European awakening to a fuller knowledge of the world. No attempt, indeed, is made to treat (except allusively) of Arab or Chinese exploration and geographical study; and it might be said that a somewhat fuller appreciation of the latter is almost indispensable for a complete understanding of the European advance to which Prof. Errera restricts himself. It might also be objected that a chapter on the exploration of the north (No. vii. "La Conoscenza del Settentrione"), including the description of the Scandinavian voyages to Iceland, Greenland and Vinland, should precede, and not follow, chapters (iv.-vi.) on the growing knowledge of Asia among Europeans during the thirteenth, fourteenth, and fifteenth centuries.

Once again, more attention might have been given to the career and first voyage (1497) of Giovanni Caboto; and, to instance a very small point, Konrad Miller's "Ebstorfkarte" is not separate from his "Mappæmundi: Die ältesten Weltkarten," but heft v. of the same. But little fault, as a whole, can be found with the way in which the author brings out, section by section, his epitome of what he defines, in his preface, as the "progressive extension of the knowledge of the superficies of our planet," down to the era of the first voyage round the world.

A special word of thanks is due to the excellent critical judgment with which the difficult voyages of the Zeni are handled—a subject hard enough in itself and doubly hard for a fellow-countryman of Nicolo and Antonio Zeno. Italians, perhaps, did more than any other people—more even than Scandinavians and Portuguese—for the advance of European trade and exploration, as well as for the perfecting of geographical science; from Antoninus of Placentia to Marco Polo and Ludovico Varthema, from Malocello and the Vivaldi to Columbus, Verrazano and the Cabots, from Flavio Gioja to Fra Mauro and Toscanelli, Italian travellers, merchants, and men of science bore a foremost share in the work of opening up the world. Among the early Portolani, the first true maps ever set forth, an overwhelming preponderance (413 out of 498) are Italian; and the whole of modern trade, with all the possibilities of civilising progress which it contains, might almost be called a discovery of Italian genius. Italian scholars of the present day may, therefore, be said to have a special claim upon the subject here discussed, as the subject has a special claim upon them; and although this *breve storia* has not the original value of Marinelli's remarkable study on the geography of the Dark Ages, it deserves a most cordial welcome.

OUR BOOK SHELF.

Die Tierwelt der Schweiz in ihren Beziehungen zur Eiszeit. Von Prof. Dr. F. Zschokke. Pp. 71. (Basel: B. Schwabe, 1901.) Price Mk. 1.20.

HERE in short compass we have set forth the relation of the flora and especially of the fauna of Switzerland to the Glacial period. Geologists have been wont to cite the occurrence of Arctic plants in the Alps and the mountains of middle Europe as strongly confirming their belief in the former prevalence of a glacial climate in what are now temperate latitudes. In his present work the author shows that, however cogent that evidence may be, it is in no degree stronger than that derived from a

study of the animal life, and more particularly of the water-life, of the Alpine lands. After briefly summarising the evidence supplied by the Arctic-Alpine plants, Prof. Zschokke refers to the former distribution of Arctic-Alpine vertebrates in the low grounds at the foot of the mountains, and gives a succinct account of the land-shells, butterflies and beetles met with in the higher Alps—many of which are true Arctic species. The major portion of his treatise, however, is devoted to the origin of the fauna of the Alpine lakes and streams. It would appear that many of the forms now flourishing in the ice-cold waters of the higher Alps hail from Arctic regions. Even in the large lakes at the foot of the mountains a glacial relict-fauna is encountered. Special reference is made to the Salmonidæ of these lakes, which are now cut off from the headquarters of their kind in the far north. They doubtless immigrated from the north during Glacial or early post-Glacial times, when such vast tracts of middle Europe were under water, or traversed by swollen rivers and great "canals," and when many of the Alpine lakes were in free communication. It is noteworthy that the Alps stopped migration further south, and that the fish in question do not occur in the Italian lakes. Eventually the limitation and interruption of water-communication with the north led to the trapping of the Salmonidæ in the great lakes. And now so long a time has elapsed since then that varieties and even new species have been developed. The fish can no longer migrate from lake to sea as their northern cousins do; but it is interesting to learn that at spawning time they still gather in shoals, as if they were about to set out on a journey. Perhaps this may be a remembrance of former conditions. Prof. Zschokke traces very graphically the changes in the life of the Alpine lands which ensued on the gradual disappearance of the extreme glacial climate. In the ice-cold waters of the higher Alps the Arctic types of life flourish at the surface, just as they do in the lakes and streams of Greenland. At the foot of the mountains, however, they are no longer met with at the surface, but have descended to the cold dark depths of the great lakes. As the mountains of middle Europe became at the close of the Glacial period "cities of refuge" to which the Arctic-Alpine flora retreated, so in like manner they have afforded shelter here and there to colonies of those Arctic forms of animal life which are still so abundant in the tarns and streams of the higher Alps, but have their headquarters in the ice-cold waters of the Arctic regions.

A Treatise on Elementary Statics for the Use of Schools and Colleges. By W. J. Dobbs, M.A. Pp. xi + 311. (London: A. and C. Black, 1901.) Price 7*s.* 6*d.*

THE author has already written an excellent book on geometrical statics, and it has been his present object to produce an elementary treatise which shall cover the well-trodden ground of the parallelogram of forces, moments and couples, centres of gravity, work, machines and friction, and at the same time shall develop the subject simultaneously from its geometrical and analytical aspect. It is sufficient to open the book almost anywhere to find evidence of originality in the treatment. Thus in the introduction the author does not leave his readers ignorant of the existence of non-rigid bodies (p. 7). Again, in dealing with the parallelogram of forces, he wisely eschews the fallacious so-called dynamical proof and gives an ingenious modification of Duchayla's proof, together with an experimental verification in which three strings stretched by spring balances, instead of being knotted together, are attached to a triangular string which forms a funicular triangle of the forces. This plan has the advantage of also showing that three forces in equilibrium meet at a point when produced. The proof of the formula for the resultant of two parallel forces is based on the "funicular" method—a change that will be most refreshing to examiners. Whenever a question is set in any examination, in which candidates are asked to find the resultant or centre of a number of parallel forces in such cases as that of a rod loaded at different points, where the answer comes out in a line by taking moments, pages and pages of work are usually sent up with the old familiar figure and proof for the resultant of *two* parallel forces: "(1) when the forces are like; (2) when the forces are unlike," and so on, finishing up with the lame conclusion that the resultant "may be found." The author's treatment of friction strikes us as a very sensible innovation, the laws of friction being based on a consideration of the angle of friction, and the coefficient of friction being defined as the tangent of this angle. There are a few points we do not altogether care about; for example, a crowbar problem on p. 119, where "perfect roughness" exists between the stone and the ground and between the crowbar and ground, and "perfect smoothness" between the sharp edge of the stone and the crowbar. In connection with such a problem, too, the author might do well in Chapter v. to say something about the direction of the reaction when an *edge* of one body rests against, but does not dig into, the surface of another. The book is copiously supplied with examples.

The Country Month by Month. By J. A. Owen and G. S. Boulger. New edition. Pp. viii + 492. (London: Duckworth and Co., 1902.) Price 6*s.* net.

THE best testimony to the appreciation of this work by the reading public is that it has reached a second edition —this being enlarged by the addition of notes written by the late Lord Lilford. Mrs. Owen, who, as editor of the delightful series of books bearing the signature "A Son of the Marshes," has had a large experience of works dealing with English country life, is responsible for the portion of the present volume treating of the habits of animals, while Prof. Boulger has written the botanical portion. The partnership may be said to have turned out in every way a success.

As the authors say in their preface, popular works on natural history absolutely swarm at the present day, but there is no other which gives in such detail the changing phases of animal and vegetable life throughout the twelve months of the calendar. It is, in fact, an expansion of Gilbert White's "Naturalists' Calendar," written in an interesting and attractive style and containing much information which should be of use to the working naturalist. In addition to the accounts of the habits of animals, there are many observations scattered through the book which, if not new, are at all events out of the common.

For instance, on p. 111 we find the remark that while the French commonly name birds from their notes, the English more generally call them after their appearance or habits. The observation (p. 418) that night-herons are increasing in number in Britain may perhaps be connected with the depopulation of country districts of which we hear so much nowadays. And Lord Lilford's note (p. 188) that frogs, small eels and young birds form the favourite food of the otter strikes us as entirely novel, since in Bell's "British Quadrupeds" we are told that "the otter lives exclusively on fish, when it can procure them." Nor do the authors confine their observations to wild animals, an interesting statement being made on p. 468 that the Angora rabbit (or at all events one individual thereof) sheds its coat entire. Misprints and other errors appear few and far between, although on p. 419 we notice "nob" standing in place of "knob." We may add that we fail to see the advantage of putting the date 1902 on a book which was in the reviewer's hands by the middle of November 1901.

To all lovers of the wild nature of our country this work should prove, not only acceptable, but invaluable.

R. L.

Strange Adventures in Dicky-Bird Land. By R. Kearton, F.Z.S. Pp. xiii + 195. Illustrated with photographs direct from Nature by Cherry Kearton. (London: Cassell and Co., Ltd.) Price 3*s.* 6*d.*

"Ugly," a Hospital Dog. With Recitations and Readings. By G. H. R. Dabbs, M.D. Pp. viii + 200. (London: C. W. Deacon and Co., 1901.) 1*s.*

Wonders in Monsterland. By E. D. Cuming. With illustrations by J. A. Shepherd. Pp. xii + 258. (London: George Allen, 1901.)

The Child's Pictorial Natural History. Part I. Pictured by C. M. Park. Pp. 24. (London: Society for Promoting Christian Knowledge, 1901.) 1*s.*

THE four books of which the titles are given above have been published at a time when people are finding suitable gift-books for Christmas presents to children who have an interest in natural history.

Mr. Kearton's volume is an attempt to express incidents in the lives of birds in an autobiographical form. The style of composition is inelegant in places, and it requires a good imagination to think of birds using such colloquialisms as: "It strikes me very forcibly we are in for more hard times," "Good old Bunny," "Guess what got her, and beware my up-to-date young friend," "Go for him, Mr. Missel Thrush." But perhaps this free and familiar form of expression will be appreciated by juvenile readers, who will certainly admire the excellent illustrations.

The first part of Dr. Dabbs's book is also in the autobiographical form, the narrator being a bull-dog who attaches himself to a hospital, and renders assistance to various members of the staff at different times. The second part of the book contains recitations and readings for odd hours.

"Wonders in Monsterland" is a nonsense-book in which the subjects are some extinct animals, disguised under such names as the Master Don, Dino Therium, Phee and Oh-don't-'op Teryx, Icky Ornis, Mackie Rodus and Ann Thropithecus. The narrative is very funny in places, and young people cannot fail to find enjoyment in reading it. The book could appropriately be described as a comic history of extinct monsters.

Popular characteristics of twelve wild animals of other countries, such as the tiger, elephant, wolf and giraffe, are described and illustrated in Mr. Park's book, with occasional Biblical references. A child might profitably read the book in connection with a visit to the Zoological Gardens.

What's What. A Guide for to-day to Life as it is and Things as they are. By Harry Quilter, M.A. Pp. xii + 1182. (London: Sonnenschein and Co., Ltd., 1902.) Price 6*s.* net.

THERE is an astonishing amount of information upon a variety of subjects in this book. The volume is, in fact, a kind of "Enquire Within for Everything," but with this difference—matters of fact are, perhaps, less frequent than matters of opinion. The introduction of this personal element imparts a lightness to the contents not usually possessed by books of reference, but after a while the reader comes to the conclusion that the editor might usefully have abridged his views and those of his contributors in order to increase the number of subjects described.

At present the book cannot be depended upon as a volume of reference; that is to say, words or terms which we expect to find in it are absent as often as not. Something is said about chemistry—not very instructive, it must be confessed—but nothing about physics; light occurs, but not the spectroscope; conservation of energy, but not conservation of matter; the moon, but not the sun; botany, but not zoology; the Hessian fly, but not the gipsy moth or Colorado beetle; hypnotism, but not hygiene; hydraulics, but not pneumatics; pathology, but not histology; geography, but not geology; equator, but not ecliptic; epilepsy, but not paralysis; and these are but a few examples of the inconsistencies of the book. In general, the information given is correct, but the following remarks upon the celestial equator form one of the exceptions to this statement:—"This does not always remain fixed, never passing exactly the same stars, but turning in 26,000 years a little nearer to the axis of the ecliptic. This causes the precession of the equinoxes, each of which occurs 20 minutes earlier in point of time than the last." A reader would be justified in speaking disrespectfully of the equator after trying to understand an explanation of this kind.

The Self-Educator in Botany. By R. S. Wishart, M.A. Pp. xiv + 226. (London: Hodder and Stoughton, 1900.) Price 2*s.* 6*d.*

THIS book is ostensibly written to enable students to obtain a knowledge of botany without receiving personal supervision and instruction. Thus the author sets before himself an onerous task the difficulties of which he has quite failed to realise. Indeed, the book displays throughout the crudest knowledge of the subject, and this is set forth in a loose and disjointed fashion without any particular arrangement or continuity of argument. Even where a good exercise is given, or an instructive experiment described, as at p. 92, the full value is lost through inadequate explanation or incomplete description. The aim of the writer to provide practical scientific knowledge in a logical manner has certainly not been attained; rather it is to be feared that the student who should work through the book will even then find that he does not know much, and most assuredly he will not know accurately.

Bastarde zwischen Maisrassen mit besondere Berücksichtigung der Xenien. By Prof. C. Correns. Bibliotheca Botanica. Pp. 53. (Stuttgart: E. Nägele, 1901.)

XENIA is the name given to the results of the crossing of the plant by a foreign pollen, exhibited in some peculiarity which appears in the seed itself, and does not—as would be the case in a hybrid—remain in abeyance until the plant which the seed produces has grown up.

Thus if a certain race of maize which produces yellow-skinned grains is crossed with pollen from a race which has violet-skinned grains, it is found that the resulting seed in many cases will be violet. It has also been discovered that this is because the potency of the pollen of the violet-skinned race makes itself effective, by means of one of the pollen nuclei, on the endosperm, and the latter acquires a violet outer layer in place of its accustomed yellowish one. In other cases of xenia other characters of the pollen-yielding parent make themselves effective on the embryo-sac—*e.g.* sugary in place of starchy cell-contents.

In the paper under review Prof. Correns has undertaken—and, be it remarked, has very successfully carried out—a large number of experiments on hybrids and xenia of maize, the results of which are set forth in great detail and illustrated by two plates of brilliantly coloured figures.

A Country Reader for Use in Village Schools. By H. B. M. Buchanan, B.A. Pp. vii + 248. (London: Macmillan and Co., Ltd., 1901.) Price 1*s.* 6*d.*

COMMON domestic and wild animals are described in this book in a simple and instructive style, capable of being understood by the elder children in village schools, and by adults who are only familiar with words of every-day life in the country. The book will impart to those who read it an intelligent knowledge of animal life in and around a farm. The illustrations, mostly reproduced from photographs, are very fine.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Histrionic Capacity of Grey Parrots.

THE capacity of the grey parrot for repeating words and sentences of human language and for imitating the cries and sounds made by other animals, both beasts and birds, is well known. The remarkable aptitude which this parrot shows for "saying the right thing at the right time" is also, I believe, well known to those who have been familiar with intelligent specimens of the bird. But I was not, until recently, aware that the bird can be not only an excellent mimic but also a good actor; and it is possible that some of your readers may be able to give other instances of what I now propose, with your permission, to relate.

My daughter had a very clever young grey parrot, which, unfortunately, died on the first of this month, after a severe illness of three weeks' duration. He was brought to my daughter straight from the nest in Africa, and had he lived another month would have been about two years old. He was a singularly clever bird, and of a charming disposition to his friends, though very shy and inclined to be hostile to strangers. He was an exceptionally good talker for his age, and showed remarkable intelligence in fitting his sayings to the occasion. He was very fond both of fruit and sugar, but I never knew him ask for sugar at dinner or for apple at breakfast. For nuts, which were kept in a cupboard in the room, he would ask at any time; and in many similar ways he showed a vivid association between the words and the things represented by them.

But the remarkable, and to me novel, power which he displayed at so young an age was that of acting. He played with a bit of wood exactly as a clever little girl plays with her doll. For example, he would take the wood in his claw and would say to it, imitating the voice and gestures of my daughter or of one of the servants, "What! are you going to bite me? How dare you? I will take the stick to you!" Then he would shake his head at the wood and say, "I am ashamed of you! Whom did you bite? Go on your perch!" Then he would take the wood to the bottom of his cage, and putting it down on the floor would hit it with his claw several times, saying, "Naughty! I'll cover you up, I will!" Then he would step back from it one or two paces, put his head on one side and say, as he looked at it, "Are you good now?"

No attempt was ever made, deliberately, to teach him this or any other of his histrionic performances. He picked them up spontaneously from his own observation and memory.

It would interest me much to know whether this capacity for acting is often found in grey parrots. D. R. FEARON.

The Athenæum, Pall Mall, S.W.

Use of the Arms in Locomotion.

I CANNOT help feeling a special interest in the two letters appearing at pages 80 and 102 of NATURE. Let anyone stand on a table and jump down, he will find that he throws up the arms to lighten the fall. Let him go quickly up or down stairs and see what use he will then make of his arms.

When I was a small boy, brought up in the country, the motions of the body indicated in these letters were natural ones to me and my brothers and sister. But as I got older I went to school, and at twelve years of age had to join a cadet corps.

Then were the natural movements drilled out of me; the body had always to be square to the front, the arms motionless by the sides. We were exercised on the flat, and one regulation quick step was practised, having one length of pace, one of time and one in stiffness.

At seventeen I went to the Royal Military College at Sandhurst, where the same system was continued, but varied, I was thankful to find, by an excellent gymnastic training.

At eighteen I became an officer and remained as such for ten years, when I retired. During the last four or five years of my service I was adjutant of my regiment and *taught* the system I have described. The British Army was indeed *smart*, it was beautiful to look at, we rejoiced in it, we were proud of ourselves.

Since my retirement in 1878 soldiers are allowed to swing the arms when marching and it is said that since the war in South Africa there are to be many *real* reforms. I shall believe in them when I see them.

At fifty-two years of age I find that in my daily walks or mountain excursions, when I am walking (1) on the flat, (2) uphill, or (3) downhill, then (1) the length of pace, (2) the time of each pace and (3) the attitude and movements of the whole body must differ in each case, so as to ensure the best work with the least possible fatigue, the least risk of falling, overstrain or other mishap. There is an art in the performance of what may seem to some the simplest actions of our lives, and it is surprising what a man can do in climbing the hillside if he knows the right way to set about it.

The British soldier is not properly taught how to march, and the war has abundantly shown that most of his drill is worse than useless.

In building a house it is usual to commence with a good foundation and finish with the roof. But what I read in the newspapers on *officially proposed* Army reform is indeed painful to me. I am a practical man and can assure you that if the British taxpayer is going to be satisfied with the creation of Army boards and Army corps, and a far too large and costly staff—the roof of the Army—and does not see to a solid foundation in a greatly improved training of the individual soldier by the *officers immediately over him—i.e.* company officers, who should be properly paid for their work—and not adjutants and sergeant-majors, he might just as well throw the millions he will be asked to expend into the Atlantic Ocean.

This is not usually the place for the discussion of Army matters, and I must stop here, hoping you will consider that what I have said fairly arises from the lead that has been given me.

But I hope I may urge in conclusion that the arms should be worked habitually by all people, solders and civilians, men and women. Medical men now recognise that in these days of civilisation the leisured classes use the lower limbs far more than the upper ones and that the true way to cure many cases of weak heart, lungs or digestion is to daily exercise the muscles of the arms, shoulders and chest, the healthy action thus set up strengthening the internal organs of the body. Serious cases of nervous disorder and brain trouble can often be successfully combated with a judicious exercise of the arms under skilled advice.

The gist of the whole matter is this. Our lives have become too fictitious; we should go to the teachings of *Nature* and endeavour to be *natural*. GILES A. DAUBENY.

Las Colondalles, Montreux, Switzerland, December 8.

The Value of the Horns in Bighorn Wild Sheep as Ear-trumpets.

IN the case of spiral-horned *domestic* sheep, as observed chiefly in the Alps, the ear is as large as is usual in sheep, and the horn (which grows homonymously, *i.e.* the right horn has a right spiral direction and the left a left) curls round the ear in such a fashion that the ear caged in the open spiral is confined to certain limits by the curves of the horn and lies in the long axis of the open spiral of the horn, from which it only now and then escapes by accident.

An extraordinary difference is seen in the wild sheep, especially to be noted in *Ovis nivicola* (for a figure and description *vide* p. 214, vol. i., Guillemard's "Voyage of the *Marchesa*"). The horns in this creature are enormous, but the ear is remarkably short, though still situated exactly in the axis of the spiral and in such a fashion that the ear appears to be at the apex of a hollow cone formed by the great spiral horn. A similar condition and relation of ear to horn is found in *Ovis montana*, the Siberian argali, and others. The form of the horn and the position of the ear enables the wild sheep to determine the direction of sounds when there is a mist or fog, the horn acting like an Admiralty megaphone when used as an ear-trumpet, or like the topophone (a double ear-trumpet, the bells of which open opposite ways) used for a fog-bound ship on British-American vessels to determine the direction of sound signals.

By taking a horn off the skull the listening ear, if properly placed, can distinguish the tick of a watch in one position best in the axis of the coil, and thus test the value of the horn for determining the direction of sounds—though no evidence of improved hearing for distance could be discovered by any such simple experiment. The functions suggested would be especially of advantage to wild sheep when feeding on mountains in mist and fog in making them more wary and difficult of approach.

Cambridge, December 7. GEORGE WHERRY.

The Influence of Temperature on the Action of Nitric Acid on Metals.

THE following simple but striking experiments illustrating the influence of temperature upon the action of nitric acid on metals may possibly be of interest to those who are engaged in the teaching of chemistry.

If three tubes containing strong nitric acid are cooled below $-10°$ C. by means of a freezing mixture of snow or pounded ice with salt, and then copper turnings added to one, granulated zinc to another and magnesium ribbon to the third, it will be found that no action takes place, the nitric acid being practically inert at this temperature. If the tubes are then exposed to air at about 22° C. so that the temperature rises slowly, it will be found that little or no action occurs until a certain temperature is reached, when a sudden and violent ebullition of brown fumes occurs, the metal rapidly dissolving and the temperature abruptly rising from 80° C. to as much as 104° C.

The critical point for this violent action lies in the case of zinc between 0° C. and 2° C., in that of magnesium between 17° C. and 19° C., and in that of copper between 19° and 21° C. Before these temperatures are reached very feeble action may occur and a few bubbles of gas be disengaged, especially in the case of the zinc. These bubbles consist partly of hydrogen gas, and if magnesium is added to cold dilute ($\frac{1}{6}$–$\frac{1}{8}$) nitric acid an active evolution of nearly pure hydrogen takes place at first, although as the solution becomes warm and the percentage of magnesium nitrate increases, the production of hydrogen rapidly diminishes. This is in somewhat striking contrast to the common statement in chemical text-books to the effect that in no circumstances can hydrogen be obtained by the action of nitric acid on metals. ALFRED J. EWART.

Meteorological Work for Science Schools.

IT has often occurred to me that the collection of data, such as those necessary for the investigation of fog distribution, might well be entrusted to the science schools over which the Technical Education Board of the London County Council exercise control.

There is, in such a research, that element of originality which is needed in the work of our school laboratories.

For interpretation the collected data may afterwards be distributed to the schools engaged in the work.

I foresee only the difficulty due to the intervention of vacations. J. V. H. COATES.

41, East Dulwich Grove, S.E., November 25.

[We have referred the foregoing letter to the Secretary to the Meteorological Council, who has been good enough to send the following remarks upon it.—Editor, NATURE.]

THE primary difficulty in the way of using science schools, as suggested by Mr. J. V. H. Coates, for the immediate purposes of such an inquiry as that of the distribution of fogs is that the schools have fixed hours of attendance to which the fogs pay no heed. To carry out such an investigation effectively the twenty-four hours must be taken into account. Of course the inquiry might be restricted to those fogs which begin or end within the hours of attendance, but that would be a very serious limitation. As confirmatory evidence, careful observations within school hours might be very useful. The necessity for securing a suitable uniformity among observers as regards the terms employed in the estimation of fogs makes it necessary, however, to proceed with caution in extending the number of separate observers.

The kind of cooperative investigation which is appropriate for organised science schools is one which can be dealt with primarily by observations at fixed hours. On special occasions it might doubtless be pursued beyond those hours in following up some definite point. Several inquiries of this nature may be suggested. For example, in relation to the fog inquiry, it is desirable to know something of the effect of wet ground during rapid falls of temperature. For this purpose an investigation of the temperature of wet soil or sand suitably exposed and its relation to the temperature of the air would be a very useful adjunct to the ordinary meteorological data. It is a part of the inquiry more suitable for science schools than for routine observation, because the conditions of exposure require examination and consideration as well as the readings of the thermometers. The hours of non-attendance could be bridged by registering minimum instruments or, in some enterprising schools, by self-recording instruments, the development and investigation of which would be in themselves a useful study.

Another line of cooperative inquiry, of much greater difficulty, suggested to me in various forms by several scientific friends, has reference to the large amount of fuel consumed daily within the London area. The combustion must of necessity raise the temperature of the air in or over London above that of its surroundings. The raised temperature should give rise on calm days to a diminished pressure and an inflowing air current. Ordinary meteorological observations are not of a sufficiently high order of accuracy to exhibit these effects, but by cooperative, and in the best sense competitive, effort between science schools in different parts of the metropolis progressive steps could be reached which might ultimately have the very satisfactory result of exhibiting quantitatively the effects of the local heating. If this ultimate purpose should not be achieved, the light thrown upon the practicable limits of observation would not be without interest.

Then, again, the chemical composition of air at different points during foggy days would be a useful inquiry. Probably the results obtained at the first attempt would not be accepted as final, but the discussion of the results from different centres would lead to more accurate determinations and ultimately to definite information of substantial value. Incidentally, such co-operative inquiries would be of very great educational influence and advantage. Supposing, for example, that it were decided to make observations of any rapidly varying element at a definite point of time, the mere carrying out of the comparison of the time-keepers at the different schools would be most instructive. The comparison of their length-standards with a view to accurate barometric measurement might be beyond the reach of available apparatus, but even the demonstration by appeal to experience that the best comparisons that could be effected with the apparatus at command, left a margin of inaccuracy of a certain defined magnitude would be sufficiently instructive to make the experiment worth trying. W. N. SHAW.

November 30.

The Date of Stonehenge.

THE remarkable paper on Stonehenge, by Sir N. Lockyer and Mr. Penrose, in NATURE of November 21 has greatly interested me. Just two years ago I was working at the subject, and wrote to Prof. Petrie to inquire what azimuth he had used for the axis of the temple in his estimate of the date, which he gives as 730 A.D. ± 200 years, with a possible date of 400 A.D. As I received no reply I employed the angle 50° 12′ E. of N., given in Mr. Edgar Barclay's "Stonehenge," 1895. With this azimuth I obtained by means of a formula, kindly supplied by Dr. Downing, F.R.S., a date of 425 A.D. I find that, for the given azimuth, even this date is too early, as I did not allow enough for refraction, &c. Applying the same formula to the figures given in Sir N. Lockyer's paper, the date comes out about 1700 B.C., as stated, so that the formula was correct, and the chief error was in the erroneous azimuth of the axis, which differs by about 38′ from the 49° 34′ 18″ so carefully determined in the published paper. Now as an increase of some 90″ in sunrise azimuth at the solstice means a decrease of some 46″ in declination and represents the lapse of about a century, the discrepancy is clearly explained. Allowing for refraction, &c., I make the present azimuth of the sun at sunrise at the solstice about 50° 26′ 21″ E. of N., the sun's declination being 23° 27′ 8″ N. Consequently since the date, 1700 B.C., the solstitial sunrise azimuth has shifted 52′ 3″ further E. and the declination has decreased 27′ 22″, representing a lapse of about 3600 years, when the appropriate formula is applied.

At the distance (250 feet) of the Friar's Heel, or Sun-stone, from the centre of the ruin, a change in azimuth of 52′ would shift a point on the axis only 3 feet 9 inches, and, as the avenue is 50 feet wide, some idea may be formed of the necessary delicacy of the measurements. The azimuthal shift of the sun himself is less than two diameters. It seems to me very improbable that any estimate of the date closer than that arrived at by Sir N. Lockyer and Mr. Penrose can be made on astronomical grounds. Recent excavations have given valuable information, but much more yet remains to be done in this direction. I may add that an exhaustive study of the "Blue-stones" (igneous rocks foreign to the locality) by the methods of modern petrology may lead to

some definite knowledge of their origin and so throw fresh light on the whole problem. C. T. WHITMELL.

Leeds, November 23.

P.S.—For sunrise (in accordance with p. 57) I take the tip of the visible sun to be 2′ above the local horizon.

Change of Pitch in certain Sounds with Distance.

SEVERAL years ago the late Prebendary Simpson, of Fittleworth, Sussex, told me of an interesting observation he had made, which some of your readers may be able to explain. While walking up and down the platform of a railway station, he noticed a peculiarity in the sound of a steam jet from an engine standing on the lines. The pitch of the sound appeared to rise as he retreated from the engine and to fall as he drew near to it. Some time after, Mr. Simpson observed the same thing again, but in this instance the noise was made by a gas flare in the open air, about which some men were at work. Since then I have found that this alteration of pitch with distance occurs with any fizzing noise of the kind, such as that of air jets, burning logs, frying fat, pouring rice or coffee beans, waterfalls, or even the rustling leaves of a single tree; with all those noises, in fact, whose sources are sufficiently localised to admit of observations of the kind being made. I found, also, on withdrawing from such a source that a point is reached after which the pitch ceases to rise, and remains practically stationary as far onward as the sound continues audible. This point is sometimes pretty definitely marked, and varies in distance from the source with different sounds, and the pitch of the stationary portion also varies in the same way. I do not think, however, that the pitch of the whole volume of sound changes, though it often appears to do so, for a similar impression is created by moving a fizzing air jet to and fro close to a wall. As it nears the wall, the whole sound seems gradually to rise in pitch and to sink again as the jet is withdrawn. But here the effect is clearly due to successive reinforcement of one part of the noise after another in the order of their wave-lengths. It is only a shifting of the point of greatest intensity, and not an actual change of pitch at all. Assuming, then, that the effect noticed by Mr. Simpson is of the same nature, that is to say, caused by a readjustment of the relative intensity of the parts, how is it to be accounted for? Is it simply a process of *sifting* by distance, the weaker groups of small noises, of which the fizzing sound is composed, dropping out of earshot in succession, as the observer retires from the source, till only the largest and loudest group is left, which last continues to be heard for the remainder of the distance without sensible change of pitch? If that is so, then the deeper tones of such noises would seem to have a proportionally shorter range of audibility than the higher ones; for, so far as I have observed, the pitch always sinks on approach to the source and rises on withdrawal from it, never the reverse way, as might be expected in the case of very bass roaring sounds. Perhaps, however, others may have noticed instances of the latter sort. The behaviour of the air-jet fizz at the wall illustrates a kind of reciprocal action, which no doubt plays an important part in the adjustment of the pitch. The tone which is loudest for the moment appears to dominate and obscure the rest, so that, near the source, where the deeper tones are most powerful, these latter, to some extent, subdue and lower the principal one, while further off, where they become enfeebled by distance, they are in their turn still more diminished by the presence of the principal far-reaching tone.

Downshire Square, Reading. FREDERICK M. WEST.

Pine Grosbeak in Berkshire.

Is it not of rare occurrence that a pine grosbeak (*Pyrrhula enucleator*) has been seen here, not on one day, but on two? I was informed this morning that Mr. O. T. Perkins had seen this handsome bird out of his window, apparently either eating beech buds or else hunting for insects on them. During this the bird was attacked by three sparrows, who began making a great noise and eventually drove him off. This morning I saw the same grosbeak, or another one, in a like manner feeding on beech. And what is more strange he was again attacked by sparrows and had to beat a hasty retreat. I may add that the bird, to all appearances, was in excellent condition, its plumage being brilliant. I wonder if any other of your readers have noticed any of these handsome but rare birds? C. M. ROGERS.

Blucher, Wellington College, Berks.

THE "ARMORL" ELECTRO-CAPILLARY RELAY.

WE commented in our notes columns a short time ago upon the announcement that a new system of wireless telegraphy had been worked out by Messrs. Orling and Armstrong. From what could be gathered from the information at that time available we judged that the method made use of earth conduction; we have since learned that this is the case and that the inventors rely upon the novel design of their transmitting and receiving apparatus for the efficiency of their results. We have had an opportunity of inspecting drawings of the receiving apparatus, and are enabled to give a description of it, though we have not seen the actual apparatus itself, but only a working model. We understand that it is proposed to read a paper shortly on the transmitter before one of the scientific societies and that in consequence it is not desired to publish the details of its construction as yet. It is to be hoped that

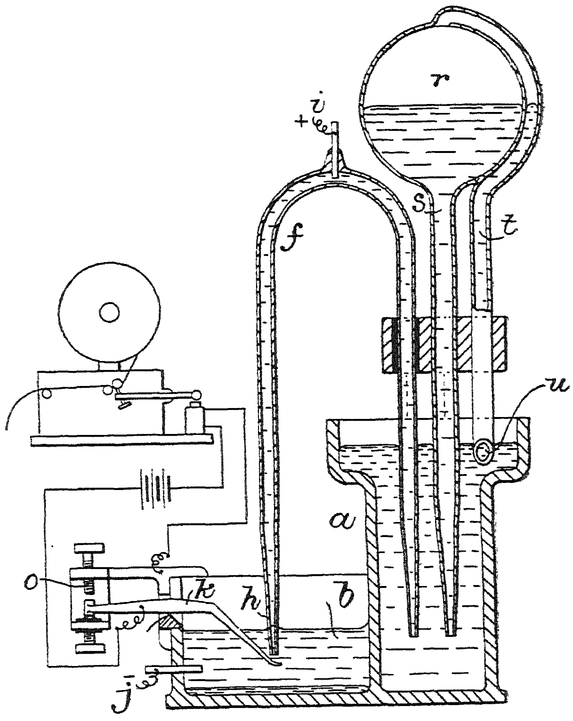

FIG. 1.—"Armorl" Electro-capillary Relay. Syphon form.

at the same time an account will be given of the experimental results obtained, with trustworthy data from which the probable value of the invention may be gauged, for as yet there is nothing to go upon but the statements of the inventors.

In the meantime we must content ourselves with giving a description of the receiver, which is of interest independently of its use with the Orling-Armstrong or any other wireless telegraph, as it could be used for the detection of any sort of electrical current. The instrument consists essentially of a capillary electrometer which is arranged so that it can actuate a relay. The extreme sensitiveness of the capillary electrometer for very small currents and low electromotive forces is well known, and the instrument is used considerably, especially for physiological work. The arrangement adopted in the present instance is shown in Fig. 1. A syphon, *f*, is

filled with mercury, one limb dipping into a vessel of mercury, *a*, and the other into a bath of dilute acid, *b*, the level of the mercury being considerably higher than that of the acid. The mercury is prevented from syphoning over by drawing out the end, *h*, of the syphon into a capillary tube. A contact is sealed into the top of the syphon at *i* and a second contact is made to the acid at *j*. When a difference of potential is set up between *i* and *j* in such a direction that *i* is positive to *j*, the capillary forces are overcome and the mercury syphons over; in so doing the mercury as it flows out of *h* falls on to a delicately balanced lever, *k*, which is thereby tilted and makes contact with a stop, *o*, thus closing a local relay circuit. The level of the mercury in *a* is maintained constant by means of the arrangement shown to the right of the syphon: a reservoir, *s*, is partly filled with mercury, which is held up by keeping a partial vacuum in *r*; when the level in *a* sinks the end, *u*, of the side tube, *t*, is opened, thus allowing a certain amount of air to enter and causing mercury to flow out until it again closes the aperture.

In a modification which has been devised the lever is arranged outside and beneath the vessel *b*, which is then provided with a capillary hole at the bottom just above the end of the lever. The bottom of the vessel is in this case covered with mercury, over which acid is poured

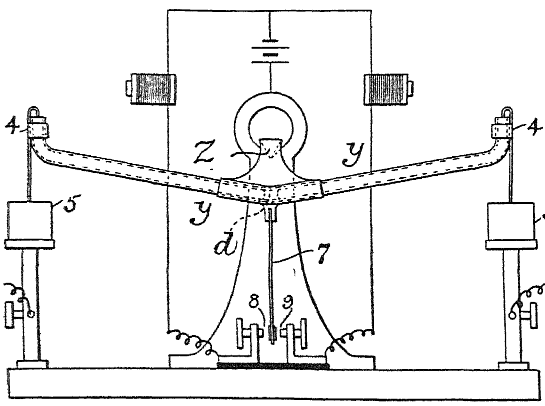

FIG. 2.—"Armorl" Electro-capillary Relay. Balance form.

until the forces of gravity and capillarity are just balanced. When more mercury syphons over a corresponding amount escapes through the hole in the bottom of *b* and actuates the lever. The lever may here be replaced by two platinum points, the falling mercury being then made to bridge the gap between the points and thus complete the relay circuit.

An alternative form of the apparatus is shown in Fig. 2. A glass tube, *y*, is balanced on a knife edge, *z*, and is filled with mercury except for a drop of acid in the centre at *d*. The current is led into this tube through metal rods, 4, 4, dipping into mercury cups, 5, 5. If a current is passed through the tube the meniscus between the mercury and acid is displaced in the direction of the current and the balance is consequently disturbed, as one arm now contains more mercury than the other; the pointer, 7, is deflected and makes contact with either the stop 8 or 9 and thus closes the local circuit. The construction is, however, said not to be so satisfactory as that shown in Fig. 1. It is claimed that the apparatus is extremely sensitive and very trustworthy in its action, and even that it could be used as a substitute for the coherer in ætheric telegraphy or the syphon recorder in cable work; but these claims remain to be established in practice.

THE OASIS OF KHARGA.[1]

DURING the last few years the Survey Department of the Public Works Ministry of Egypt has shown considerable activity in the prosecution of investigations connected with the geological survey of the valley of the Nile, and the publications which it issues from time to time show that the results which it obtains from them are of great interest and importance. Until comparatively recently the conclusions formed about the stratification of Egypt and its past geological history were based upon researches which were undertaken without sufficient preparation, often indeed without sufficient knowledge on the part of those who made them, and the statements made on the subject were often confusing and sometimes contradictory. Under the direction of Sir W. Garstin, however, things have taken a turn for the better, and the geological publications prepared with his sanction and approval really help to put our knowledge of the geology of Egypt upon a sure base.

The publication before us, by Mr. John Ball, is interesting from every point of view and reflects great credit upon the department to which he belongs. There is much in it, of course, which will appeal only to the engineer and geologist who are concerned with the practical administration of the district of the Oasis of which it treats, but there is also much which will claim the careful attention of the archæologist and antiquary. The work is divided into four chapters, which treat of the surveying methods employed and their general results, of the roads between the Nile Valley and the Kharga Oasis, and of the topography and geology of the Oasis; besides these we have an introductory chapter, five appendices, nineteen maps and plates, and sixteen illustrations. The book is satisfactory because it tells us, not only what are the results which have been obtained, but also *how* they have been arrived at, and the plans, maps, and illustrations enable the reader to follow these results with ease.

The Oasis of Kharga has been a source of wonder to untold generations of men, and the curiosity of all cultivated students has been roused more and more as each traveller has returned from it and unfolded in his written descriptions of the place stories of its people and antiquities. Concerning the origin of the Oasis experts are in doubt, but Mr. Ball thinks that its whole area has undergone disturbance which has resulted in folding and faulting; and since the faults affect the highest rocks on the plateaux, it is clear that they took place since the deposition of all the strata which are now found in the Oasis, the calcareous tufa, of course, excepted. The date of the folding and faulting cannot be fixed precisely; all that can be said from the examination of the Oasis itself is that it took place since Lower Eocene times. It is possible that it may be connected with some younger faulting seen in the Nile Valley at the First Cataract, but we have as yet insufficient information for a definite connection of this faulting with the folding of the strata in the Oases. The faulting produced much cleaving and crushing of the rocks, but we have to find out what was the particular agency which excavated and carried away the cracked-up limestones, and to account for disintegration and removal of hundreds of cubic miles of limestone rock, some of it being of considerable hardness. It is probable that the excavation was begun by the action of water, and that after this ceased, owing to a total change in the climatic conditions, *i.e.*, the change from a moist climate to a dry one in Egypt, the work was continued and is still going on by the agency of wind and sand. The superficial erosion both of the Oasis and of the hills within and round about it is due to wind-borne sand, but this has never been realised by travellers, for they have usually visited

1 "Kharga Oasis; its Topography and Geology." By J. Ball. (Cairo, 1900.) Pp. 82.

the Oasis in the calm winter and spring months. Even at the present day the Oasis is enlarging its boundary, and the surface of the plateau is being ground away by sand, and the underlying clays on the faces of the scarps are being steadily excavated. The water in the Oasis is derived from the rainfall of the highlands in the interior of Africa, which, coming by way of the permeable underground strata, appears where these strata rise to the surface or are pierced by wells, though strangely enough the wells are chiefly on the down-throw side of the fault, *i.e.* to the eastward of it.

The history of the Oasis of Kharga in its relation to Egyptian history is full of interest in every way. That it was well known to the Egyptians under the Early Empire is tolerably certain, for from the inscription of the officer Una who made expeditions into the deserts of Libya and the Sûdân we know that the tribes of the districts in the neighbourhood of it were in the habit of waging war against each other. Under the eighteenth dynasty the Oasis of the North and the Oasis of the South were subject to the great kings Thothmes III. and Amenhetep III., and there is no doubt that a considerable trade between them and Egypt was in existence in still earlier times. Every now and then the tribes revolted against the rule of Egypt, but their triumph was short-lived, for Egyptian soldiers appeared and the rebellion was stamped out in a peculiarly firm manner, and the trees were cut down and the gardens destroyed. In the twenty-second dynasty the Oases were still reckoned as a part of Egypt, and under the Persians Kharga was chosen by Darius I. as the site of the fine temple which he built there; this temple was finished by Darius II., and must have been, judging by its present remains, a striking and a remarkable object. It is curious to note that the Egyptians at one time believed that the souls of the dead made their way to the Oases, and it is obvious that the green fields and gardens full of vines and palm trees easily connected themselves in their minds with the Elysian Fields, wherein every Egyptian hoped eventually to live. Before the end of the twenty-sixth dynasty Kharga was used as a place of banishment for criminals and evil doers, and the Romans found it necessary to maintain a garrison at Hibis, the chief city of the Oasis, to keep order. Christianity was introduced into the Oasis by one of the Apostles, who is said to have died and been buried there, and when Nestorius was banished there A.D. 435 he found flourishing Christian communities at several places in the Oasis who would, no doubt, accord him a far from hearty welcome.

Mr. Ball has consulted the works of travellers such as Cailliaud and Hoskins, Rohlfs and Brugsch, and although he has little new to say about the temples and other buildings which they described, his notes on the temples of Hibis, Nadura, Kasr al-Guehda, Kasr Zaiyân, Kasr Dûsh, or Kysis, are most useful, especially as they are accompanied by clear plans. His remarks on the Christian antiquities are somewhat meagre, but then he is an engineer and not an archæologist. In the next edition of his work the paragraph on p. 78 in which he states that the Christian tombs are those of the followers of Nestorius should be modified, for we know on the authority of Christian tradition and writings that there were several congregations of Christians in the Oasis of Kharga one or two centuries before the time of Nestorius, and it is evident that they must have left graves behind them. The tombs may then as well belong to the third and fourth as to the fifth and sixth centuries; and seeing that Nestorius was a violent opponent of the Monophysites in Egypt, it is more than doubtful if he had any followers at all among the Jacobite Christians of Kharga. But these considerations in no way affect the value of Mr. Ball's engineering work, though they do show that an engineer is not also necessarily an archæologist.

SIR WILLIAM MACCORMAC, BART., K.C.B., K.C.V.O.

SIR WILLIAM MACCORMAC, whose death occurred suddenly and unexpectedly on the morning of December 4 at Bath, where he had gone for treatment of an illness which his intimate friends, although feeling considerable anxiety on his behalf, little thought would end so tragically, was one of the most prominent figures in the medical profession in London. He was the son of a well-known Belfast physician, Dr. Henry MacCormac, the author of such philosophical works as "The Philosophy of Human Nature," published in 1837, and "Aspirations from the Inner Life," in 1860, as well as of works on the nature, treatment and prevention of consumption, which attracted much attention at the time and have come again into notice recently as having anticipated the modern doctrine of the open-air treatment of tubercular disease. Sir William MacCormac was born in Belfast on January 17, 1836; he was educated in his native city and graduated as M.A. of the Queen's University of Ireland in 1858. He subsequently studied medicine in Dublin and Paris and became a Fellow of the Royal College of Surgeons, Ireland, in 1864, entering at the same time into the active work of his profession as surgeon to the Royal Belfast Hospital, a post which he held until 1870.

On the outbreak of the Franco-German war he returned to Paris and offered his services to the French Red Cross Society, "*La Société de Secours aux blessés militaires.*" His offer was accepted and he was ordered to Metz, where he was taken prisoner, released and sent back to Paris. It was then that, along with Mr. Furley, now Sir John Furley, and Dr. Philip Frank, he came in contact with Dr. Marion Sims and other Americans (who had come over with a large quantity of material, but with little or no funds), and established the Anglo-American Ambulance with the financial assistance of the National Aid Society, which had been formed in London at the beginning of the war. The Ambulance proceeded at once to Sedan under the charge of Dr. Marion Sims, with MacCormac as second in command, and arrived there in time to take an active and prominent part in the decisive battle of the campaign. At Sedan MacCormac was in his element, and it was there that he laid the foundation of his future greatness. His "Notes and Recollections of an Ambulance Surgeon," published in 1871, vividly described his experiences of the battle and the absorbing, incessant work of a surgeon in the midst of carnage. The book has been translated into German, French, Dutch, Italian, Russian and Japanese, and has made his name a household word amongst the military surgeons of Europe. When the pressure of the work in Sedan was over MacCormac returned to England, and with the assistance of the influential committee of the National Aid Society was appointed to the staff of St. Thomas's Hospital, which had just been opened. He took the Fellowship of the Royal College of Surgeons, England, at the same time, and remained associated with St. Thomas's in the varying capacities of assistant surgeon, surgeon and lecturer on surgery in the medical school, and consulting surgeon and Emeritus lecturer on clinical surgery. He also held many other consulting appointments in London and was examiner in connection with the naval and military medical services.

His reputation as an authority on gunshot wounds was not allowed to lapse for want of opportunity. In 1876 he accompanied the late Lord Wantage, then Colonel Loyd-Lindsay, to Alexinatz during the war between Servia and Turkey. His period of stay at the seat of war was, however, brief, as he and his companion were obliged to take flight with the retreating army. In 1899 he was appointed a consulting surgeon to the field force in South Africa, and saw much of the results of the earlier and fiercer struggles of the war.

The European fame of Sir William MacCormac as a British surgeon almost equals that of Lord Lister. Honours were showered upon him by the Governments and learned societies of foreign States, and his friends included some of the most famous continental surgeons of modern times. Stromeyer, Esmarch, Langenbeck, Coler, Billroth, Mundy, Larrey, Pozzi and many others knew and admired his work and valued his friendship, while his commanding presence was recognised and acclaimed in all assemblies of military surgeons, wherever he went. Indeed it may be said of him that no man in this country kept up his connection with colleagues abroad as he did. His hospitality to them and to all his friends was proverbial.

MacCormac's minor contributions to the literature of his profession are chiefly found in the St. Thomas's Hospital reports and in the medical journals. His larger works, in addition to articles on "Gunshot Wounds" in Heath's "Surgery," "Diseases of the Bones and Joints" in Quain's "Dictionary of Medicine," and "Hernia" in Treves' "System of Surgery," are "Antiseptic Surgery," the development of an address delivered at St. Thomas's Hospital, published in 1880 and translated into French and Russian, and "Surgical Operations," the first part of which, the ligatures of arteries, was published in 1885, and the second, operations on joints and nerves, in 1889. With the exception, however, of his "Notes and Recollections of an Ambulance Surgeon," none of his writings are likely to have the same historical interest as his father's work on consumption, and it can scarcely be claimed that the success of his career was due to any exercise of a power for scientific investigation, although he undoubtedly possessed that power. He was skilful as an operator, lucid and loved as a teacher; but it was his wisdom in counsel, the sanity of his judgment, the common sense of his oratory, rather than any marked advances made by him in the science and art of surgery, that gained him the unique distinction of being elected president of the Royal College of Surgeons four times in succession. He was knighted in 1881 for his services as general secretary of the Seventh International Medical Congress in London, and was created a baronet on the occasion of the Queen's Jubilee in 1897. He was appointed a K.C.V.O. in 1898 and a K.C.B. in February last after his return from South Africa. He was appointed Surgeon-in-Ordinary to H.R.H. the Prince of Wales and Honorary Sergeant-Surgeon to the King on his Majesty's accession to the Throne. The last year of his life was somewhat saddened by the controversies that arose in consequence of his outspoken support of the Army Medical Service during the war. He felt bitterly how much the country had been misled by those who decried the work of the Army medical officers and who knew little of war and still less of the surgical possibilities of war.

Sir William MacCormac married, in 1861, Miss Charteris, of Belfast, but had no family. Lady MacCormac, who was his life-long companion and accompanied him wherever he went, survives him.

The funeral of Sir William MacCormac took place on Monday, the first part of the funeral service being observed at the church of St. Peter, Vere Street. His Majesty the King was represented by General Godfrey Clerk. The French and German Embassies in London were represented, respectively, by M. E. Daeschner and Major Count von Bredow. The French Consul-General in London was also present. The council of the Royal College of Surgeons was represented by Mr. J. Langton, Mr. H. G. Howse, Mr. T. Bryant, Mr. A. Willett, Mr. R. Harrison, Mr. H. T. Butlin and Mr. W. W. Cheyne. Prof. C. Stewart, conservator of the museum, was also present, as well as many others connected with the Royal College of Surgeons and the profession of surgery. The Royal College of Physicians was represented by Sir W. S. Church (president), Sir Dyce Duckworth (treasurer) and Dr. E. Liveing (registrar). Of St. Thomas's Hospital, with which Sir W. MacCormac had been so long connected, there were many representatives. Among other institutions represented were the French Hospital, the Army Medical Department, Medical Department of the Navy, the Italian Hospital, Queen Charlotte's Hospital, the University of London, the British Museum and the British Association. Among many others present were Lord Lister, Sir William Broadbent, Sir Norman Lockyer, Sir Thomas Smith, Sir Lauder Brunton, Dr. T. Seymour Tuke, Dr. P. H. Pye-Smith, Major-General Sir Owen Tudor Burne, Mr. Andrew Clark, Sir J. and Lady Fayrer, Dr. and Mrs. D'Arcy Power, Sir F. and Lady Semon, Lady Dyce Duckworth, Sir A. S. Wells, Sir S. Wilks, Sir J. W. Williams and Sir James Blyth.

THOMAS MEEHAN.

THE eminently successful life of Thomas Meehan, distinguished as a gardener, a botanist and a citizen, closed on November 19. Mr. Meehan was born in London in March 1826, and received what little schooling he had in the Isle of Wight, where his family had settled. Leaving school at an early age, and displaying a marked aptitude for gardening, he was employed under his father in the gardens of Colonel Francis Vernon Harcourt, at St. Clare, near Ryde. When only fourteen he succeeded in raising the first hybrid Fuchsia, St. Clare, and in appreciation of a paper which he published on Rubus was elected, when only nineteen, a member of the Wernerian Society. After holding various gardening appointments he entered the Royal Botanic Gardens, Kew, in 1846, on the recommendations of Dr. Bromfield and Prof. C. C. Babington. At Kew, where he stayed a little more than two years, he made the acquaintance of Berthold Seemann, with whom he was a candidate for the appointment of botanist to the *Herald* expedition. On leaving Kew he became head-gardener to the Earl of Shrewsbury at Alton Towers, a post which, owing to his religious opinions, he was soon obliged to relinquish. Though offered tempting inducements to remain in his native country, Meehan determined to make America his home, and reached Philadelphia in March 1848.

His career there opened in the humble position of a nursery labourer. But advancement quickly followed. He obtained employment in the famous Bartram Gardens of Philadelphia, and in 1853, with remarkably little capital, established a nursery business of his own, which, in conjunction with his sons, he continued to the end of his life. He was a voluminous writer on horticultural and botanical subjects. He founded the well-known *Meehan's Monthly*, and half a century ago published his "Handbook of Ornamental Trees." In 1878-79 appeared "The Native Flowers and Ferns of the United States," a handsome illustrated work in two large octavo volumes. His botanical papers contributed to various scientific journals, and chiefly to the *Proceedings* of the Academy of Natural Sciences of Philadelphia, number considerably more than a hundred. Enthusiastic in all his undertakings, Meehan became a leading member of the Philadelphia Academy, of which he was vice-president for more than twenty years; a representative of his ward in the Common Council, and a member of the local school board; while his botanical attainments secured for him the proud position of Botanist to the Pennsylvania State Board of Agriculture.

Reviewing his life's story, the heroic toil, the splendid energy, the brilliant success achieved in spite of all obstacles, a tribute of praise such as this, and from a far wider world, is due to the memory of Thomas Meehan.

S. A. SKAN.

THE PHOTOGRAPHS OF NOVA PERSEI.

REFERENCE has already been made in NATURE to the important photographs of the nebula associated with Nova Persei obtained by Mr. Ritchey at the Yerkes Observatory with the 2-foot reflecting telescope, the exposure being four hours. The *Astrophysical Journal*

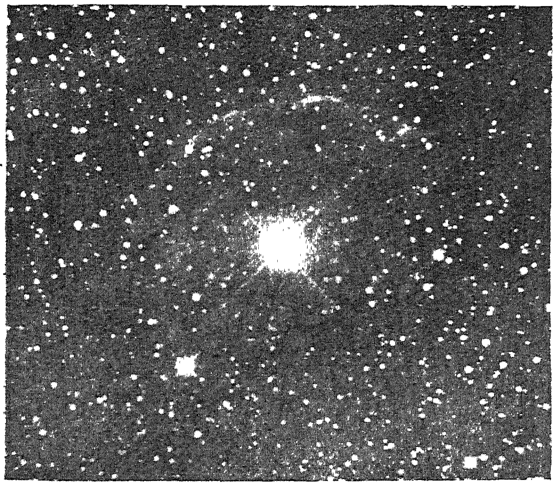

FIG. 1.—The Yerkes Photograph, September 20.

for October contains an enlarged (five diameters) copy of the photograph and a diagram made from the original negative, which are now reproduced.

Still more recently the results secured at the Lick Observatory by Mr. Perrine with the Crossley 3-foot reflector with an exposure of more than seven hours, which were telegraphed over in the first instance, have now reached us in some detail. The communication (*Bulletin* No. 10) is accompanied by a diagram which shows remarkable changes of position in the more pronounced condensations. This diagram is referred to as follows:—

"The four masses of nebulosity are designated by the letters A, B, C, D; the positions which the centres of figure occupied on September 20, as shown in the reproduction from Mr. Ritchey's photograph, are occupied by the left-hand or north-west end of each of the short lines; the positions on November 7-8 are occupied by the right-hand or south-east ends of the lines.

"The line drawn between these positions for each condensation indicates the direction and amount of motion in the interval of forty-eight days. Condensation A is much the best adapted for accurate measurement, from its greater strength and from its forked appearance; condensations B and C are not quite so good for measurement as A, but still are very determinate; but while condensation D is the brightest of all, it is large, and so near the image of the Nova as to make its amount and direction of motion somewhat uncertain.

"It will be seen that the displacements agree well and amount to about $1\frac{1}{3}'$. The directions are not so consistent and could perhaps be explained by irregular motions in the nebulous mass, by a general translation of the nebula in one direction or by a spiral motion. It is certain, however, that the motion is not radial.

"The amount of motion is almost incredible, being no less than at the rate of 11′ per year. The greatest displacement (proper motion) in the stellar universe, so far observed, is less than 9″ per annum."

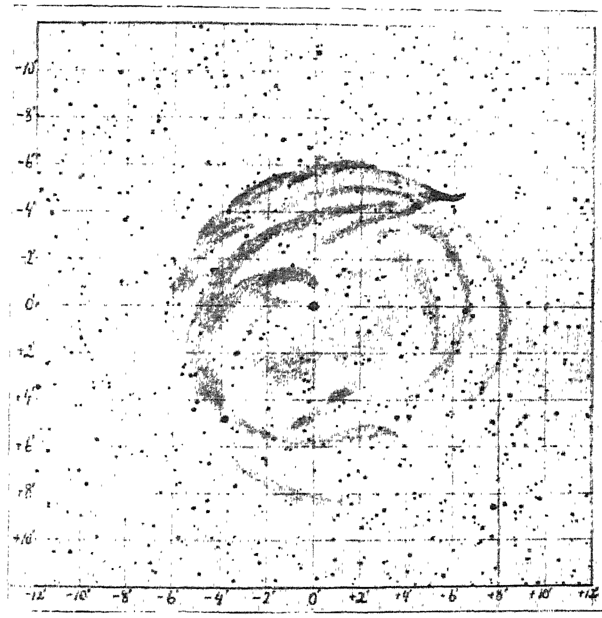

FIG. 2.—Drawing showing details and condensations.

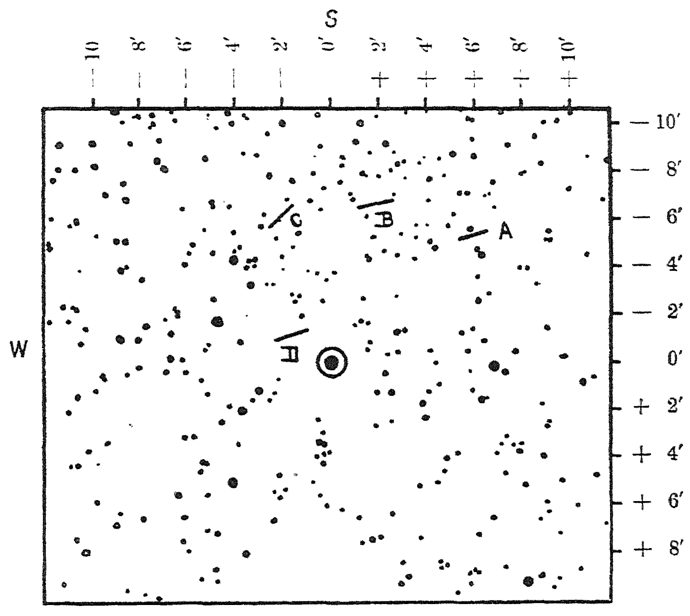

FIG. 3.—Diagram showing changes in position in the condensations as determined by the later observations at the Lick Observatory on November 7-8.

The note then goes on, "such an exceptional velocity as is here indicated leaves little doubt of the intimate connection of this nebulous matter with the Nova and its outburst. It is, perhaps, too soon to say just what bearing the foregoing observations will have upon the explanation

of the phenomena connected with new stars. It would seem, however, that such great velocities pointed rather to a violent collision of some sort than to an outburst within a dark and comparatively cool body; but whether a collision of a solid body with another, or the passage of a solid body through a gaseous nebula or a swarm of meteorites is uncertain."

It appears to me that the full significance of the recent observations has not been grasped by those who have commented upon them. It seems difficult to imagine that most of the new stars, like the bright-line stars and bright-line nebulæ, are *not* at the distance of the Milky Way as well as in its plane. If this be so, then this distance is enormous. Let us assume—the assumption is a moderate one—that it is represented by a parallax of half a second, and see how it works out on the two-minute squares marked in the diagrams.

At the Nova situated at such a distance, 1 minute of arc represents about 120 times the sun's distance from the earth.

The apparent movement of the condensations is stated to have been $1\frac{1}{2}$ minutes in 48 days, say, approximately, 1 minute in a month, say, again, four times the distance of the sun in a day.

I do not say that such rapid translations of masses of matter are impossible, certainly there are no precedents for them; but my point is that there is absolutely no necessity for the assumption of such movements, and that the apparent change of position of these condensations can be explained otherwise than by movement. Indeed, such an explanation is not hard to seek when the meteoritic theory of new stars is closely considered in all its aspects. It is a well-known fact that the majority of new stars that have been recorded in more modern times, when the spectroscope has been available for their study, have ended by becoming nebulæ. The meteoritic theory explains the appearance of a new star by the interpenetration of two or more swarms of meteorites, a nebula being the representative of an ordinary great swarm, a comet near the sun being a representative of a small one disturbed by tidal action. The appearance of a new star is produced by the luminosity depending upon the celestial clashing. It is not difficult to conceive a system of several swarms of meteorites all performing their individual orbits, and so long as no two systems collide, the whole system will be invisible; but should a collision occur they will at once become visible, and the more violent the collision the brighter will be the light and the greater will be the luminosity of the "new star" which makes its appearance to chronicle the event.

Now suppose a nebula invaded, not by one, but by many swarms, under such conditions that the collision effects vary very greatly in intensity. In the present case the most violent one we began to know about some months ago; it constitutes Nova Persei. The least violent ones occurring in other parts of the disturbed nebula, almost immeasurably removed, *i.e.* more than 700 solar distances away, we only learn of from the recent photographs. The disturbances they chronicle are so feeble that to see the effect of them 7 hours' exposure with a 3-foot reflector are necessary, hence they soon die out; while they are dying other disturbances in other parts of the nebula arise. There is probably, therefore, no question of motion from place to place, we are dealing simply with different disturbances occurring in different places.

It is impossible to think that the great nebula which has now been photographed while the new star is still in being did not exist there a few months ago; and it is important, further, to remark that the nebulous matter already photographed in the region round the Nova is very probably only a portion of the actual amount of matter existing there, and that if the disturbances continue, more of the remaining portion may become visible. This, in fact, seems already to have been established, for Ritchey found later that the nebula "seems expanding in all directions." At the same time it may be stated that Campbell notes that the condensation D has remained unchanged, while there has been a further "movement" in the case of A and B, the "movement" of C being doubtful. There seems little doubt that later photographs will throw light on this question, but a matter to be regretted in this connection is that no photographs are available for the period during which the well-marked variability of the Nova was observed. These occasional outbursts of light were, we can now imagine, due to other disturbances of the nebula intermediate in intensity between that which caused the Nova itself and the other exceedingly faint ones now being photographed.

One important conclusion can, at any rate, be deduced from the Lick photographs, and that is that such explanations as explosions on solid globes, worlds on fire, volcanic eruptions, &c., must be considered less probable now that a great nebula is shown to be associated with many disturbances of very varying intensities. Formerly we had to wait for the death of a new star before the appearance indicating the existence of a nebula was manifested, and hence arose the idea that a star changed into a nebula, thus reversing the ordinary process of evolution.

NORMAN LOCKYER.

NOTES.

THE four Nobel prizes were distributed at Stockholm on Tuesday evening before a distinguished audience, among whom were the Crown Prince and other members of the Royal family o Sweden. Each prize was of the value of 200,000 francs. The prize for medicine was awarded to Dr. E. A. Behring, the prize for chemistry to Prof. J. H. van 't Hoff, the prize for physics to Prof. W. K. Röntgen, and the prize for literature to M. Sully Prudhomme.

IT is officially announced that the Board of Admiralty have received with much regret the resignation by Sir William H. White, K.C.B., F.R.S., in consequence of ill-health, of the appointment of Director of Naval Construction, which he has filled since 1885 with great distinction. They have appointed as his successor Mr. Philip Watts, F.R.S., who has held during the same time the post of director of the war shipbuilding department of Messrs. Sir William Armstrong, Whitworth and Co., Ltd., and naval architect to the company. Mr. Watts has done much original scientific and experimental work in connection with investigations of the stability of ships and floating bodies, the oscillations of ships in still water and amongst waves, and the propulsion and manœuvring powers of ships.

THE Berlin correspondent of the *Times* states that the estimates for the German Army include a vote for the new military technical college which the Government will open in the course of next year. The necessity for some such institution has been impressed upon the military authorities by the advancing scientific requirements of modern warfare, which are now too numerous and too varied to be provided for adequately by the resources at the command of the existing Staff College. There are branches of technical knowledge which, although they cannot strictly be classed as military, are nevertheless indispensable for the soldier. Among such subjects are steam-power, electricity, mechanics, the construction of boats and bridges, and the establishment of means of communication. In recognition

of this fact the college which is shortly to be opened will have for its objects the extension of general technical knowledge in the Army and also the special technical training of engineer officers, as well as of those officers who desire to prepare themselves there for a career in the railway, ballooning and other special departments of the service. It is expected that the college will be opened on October 1, 1902. The ordinary annual expenses are estimated at 300,000 marks.

AMONG the lecture arrangements at the Royal Institution, before Easter next year, we notice the following:—Prof. J. A. Fleming, six lectures (adapted to young people) on waves and ripples in water, air and æther Dr. A. Macfadyen, six lectures on the cell, its means of offence and defence, immunity; Mr. W. N. Shaw, two lectures on the temperature of the atmosphere, its changes and their causes; Prof. E. B. Poulton, two lectures on recent researches on protective resemblances, warning colours and mimicry in insects; Dr. A. S. Murray, three lectures on recent excavations at Delphi and in the Greek Islands; six lectures on some electrical developments, by Lord Rayleigh. The Friday evening meetings will commence on January 19, when Lord Rayleigh will deliver a discourse on the interference of sound.

A CIRCULAR just issued announces that the Andrew Carnegie research scholarship or scholarships, of such value as may appear expedient to the Council of the Iron and Steel Institute from time to time, will be awarded annually, irrespective of sex or nationality, on the recommendation of the Council. Candidates, who must be under thirty-five years of age, must apply, on a special form, before the end of March to Mr. B. H. Brough, the secretary of the Institute. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students who have passed through a college curriculum or have been trained in industrial establishments to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. There is no restriction as to the place of research which may be selected, whether university, technical school or works, provided it be properly equipped for the prosecution of metallurgical investigations. The appointment to a scholarship will be for one year, but the Council may at their discretion renew the scholarship for a further period instead of proceeding to a new election. The results of the research will be communicated to the Iron and Steel Institute in the form of a paper to be submitted to the annual general meeting of members, and if the Council consider the paper to be of sufficient merit, the Andrew Carnegie gold medal will be awarded to its author.

THE death is announced of the Rev. Hugh Alexander Macpherson, of Glendale, at the early age of forty-three. Mr. Macpherson was an authority on the fauna of the lake country, and had published an elaborate work on the subject, "A Vertebrate Fauna of Lakeland, including Cumberland and Westmorland, with Lancashire North of the Sands." He was also the author of a book entitled "British Birds."

THE "Association Internationale des Botanistes," founded in August at Geneva, having purchased the *Botanisches Centralblatt*, will continue it as the organ of the Association. It will be published by Messrs. Brill, of Leyden, and the first number will be issued on January 1, 1902. The journal will appear weekly and will contain abstracts of all important publications on botanical subjects. The cooperation of a large staff of highly competent special editors in various countries has been secured, and the abstracts will be published in English, French or German. The annual subscription of members of the Association is 25*s*., and they will receive the journal post free. Applications for membership may be made to Dr. J. P. Lotsy, Oude Rijn, 33A, Leyden, Holland, who acts as the editor-in-chief. A feature of the journal will also be a very full list of the current publications in the science. In order to assist the editor, authors of botanical publications are invited to send copies of their works to him, or to the special editor in their own branch, in their country. The special editors for Great Britain are as follows:—Algæ, Miss Barton, British Museum (Nat. Hist.); Fungi, Mr. Massee, Royal Gardens, Kew; Archegoniatæ, Mr. A. Gepp, British Museum (Nat. Hist.); Phanerogams, Mr. Daydon Jackson, 21, Cautley Avenue, Clapham Common, S.W.; Cytology, Prof. Farmer, Roy. Coll. of Science, S. Kensington; Physiology, Prof. Vines, Headington Hill, Oxford; Morphology, Dr. W. H. Lang, University, Glasgow; Palæontology, Prof. Scott, Old Palace, Richmond, Surrey.

A NEW form of stereoscopic fluoroscope, worked out by Mr. E. W. Caldwell, is described by him in the New York *Electrical Review* for November 16. The method employed is the same as that first brought forward by Dr. McKenzie Davidson, but some modifications are introduced which, it is said, make it more easy to operate. Instead of using two different tubes as the sources of Röntgen rays, a single tube is used into which two antikathodes are sealed. The tube is excited by an alternating current by connecting it to the secondary coil of a transformer the primary of which is connected to the street mains through a Caldwell liquid interrupter; when a direct-current supply only is available, a small rotary converter is used to give an alternating current. The antikathodes are thus alternately sources of Röntgen rays, and the shadows these cast on the fluoroscope screen are viewed through a rotating shutter which only allows the right eye to see the shadow from one antikathode and the left eye that from the other. The shutter is rotated by a synchronous motor supplied from the same source of current as the X-ray tube. The speed of rotation is such that 7200 shadows are cast per minute, 3600 of which are visible to the right eye of the observer and the alternate 3600 to his left eye; the result is that the radiograph is seen as a continuous image showing the shape and space relations of the object examined. The fluoroscope screen and rotating shutter, with its motor, are mounted together in a portable form in order that in surgical cases they may be conveniently adjusted to suit the case of the patient.

THE Royal Meteorological Society has published in its *Quarterly Journal* an account of the bequest made to it by Mr. G. J. Symons of such of his books, pamphlets, maps and photographs, copies of which were not already possessed by the Society, and exclusive of works specially relating to rainfall. As a result, some 6200 books and pamphlets and 900 photographs have passed into the library of the Society, including some valuable works on rainfall to which Mr. H. Sowerby Wallis generously yielded his prior claim. In addition, Mr. Symons bequeathed to the Society various medals, &c., and a sum of 200*l*., which has been utilised in providing accommodation for this valuable legacy. Mr. Symons's library was almost entirely meteorological; many of the volumes were exceedingly scarce and of very early date, and he endeavoured to procure a copy of each edition published. Nine of the works belong to the fifteenth century, 128 to the sixteenth and 214 to the seventeenth centuries. One of the earliest daily records of weather kept in London (1668–1689) is contained in a work entitled "Nauticum Astrologicum: or the Astrological Seaman," by John Gadbury (London, 1710). Another early record in London is "A Meteorological Journal kept in Paternoster Row" (1786–1792), by W. Bent. Mr. Symons's note is, "Excessively scarce. I never saw or heard of another copy." A later publication, carrying the

observations down to 1800, and containing a summary of the previous observations, is not so scarce. Although not included in the bequest, the Society wisely obtained by purchase a bibliography compiled by Mr. Symons containing about 60,000 titles of meteorological and kindred subjects.

AN International Exhibition of Automobiles was opened at Paris on Tuesday. Among the exhibits of scientific interest are steerable balloons and motors to drive them. The cigar-shaped balloon "Ville de Paris," which M. Deutsch proposes to try next spring, is shown, and also a steerable military balloon invented by Major Renard.

PROF. G. VICENTINI has communicated to the *Atti* of the Venetian Institution a paper on the supposed efficacy of canon-firing in preventing hailstorms. In this paper the author briefly reviews the work of the second International Congress held at Padua, and his general conclusion is that the matter requires to be studied in a more scientific and statistical manner than has been hitherto done. For this purpose it may be desirable on account of expense to restrict the investigation to a limited region, but in the absence of more exact investigations it is thought that the experiments hitherto carried out can be hardly regarded as conclusive.

WE received a few days ago the Report, dated March 1901, of the International Association for Promoting the Study of Quaternions and Allied Systems of Mathematics. From the address of the president, Prof. C. J. Joly, of Dublin, we learn that the Association was founded about the year 1900, at the instigation of Mr. S. Kimura, of Japan, and Dr. P. Molenbroek, of the Hague, and Sir Robert Ball was its first president. The society proposes to publish a bibliography of the subject, and a report on the position of quaternions and allied branches of mathematics in the curricula of universities and colleges throughout the world is also projected.

WE have received from the author, Mr. G. W. Cole, a copy of a pamphlet entitled "Bermuda and the *Challenger* Expedition," being a bibliography of the results obtained by that expedition at and near Bermuda. Owing to the establishment of a biological station, each year witnesses the arrival in the islands of an increasing number of zoologists, and it is for their use that this useful pamphlet has been chiefly compiled.

THE observations of Herr E. Wasmann on the relations subsisting between the staphilinid beetles dwelling parasitically (or commensurally) in the nests of ants and termites are already classic. The subject is further elaborated in a paper (the first of a series) which appears in the *Biol. Centralblatt* for November, in which the author suggests that in some of these parasites we have instances of the actual evolution of species going on before our eyes.

OUR contemporary *Die Umschau*, of December 7, contains an interesting summary, by Dr. F. Knauer, of recent investigations —especially those of E. Wasmann—connected with the life-history of ants and termites, particular attention being directed to those insects living in commensalism in their nests, and the plants they cultivate. Attention is first directed to the so-called "crippled" or "pseudogynous" ants of certain species, which have the head and abdomen of a worker and the body of a female. Following this, the author refers to the curious circumstance that not only do the beetles living in commensalism with ants show an extraordinary enlargement of the abdomen, but that the same feature characterises the recently-discovered flies of the genus Termitoxenia. The paper concludes with a notice of the funguses and other plants cultivated by ants.

THE new editions of Darwin's "Descent of Man" and "Origin of Species" which have recently been published by Mr. John Murray are the most remarkable specimens of cheap and authoritative scientific literature which have come under our notice. Either of the books named can now be obtained in the form of a well-printed and neatly-bound volume for half-a-crown, and a popular edition of the "Origin of Species" has been published at the price of one shilling. No one interested in the great problems of natural history need, therefore, be without the two works which determined the direction of inquiry in the last century and still exert a profound influence upon biological thought. It is worth while to remind naturalists that though the copyright of the "Origin of Species" has now expired, only the imperfect edition can be reprinted without the authority of the author's executors. The only complete and authorised edition is that published by Mr. Murray.

THE Report for the year 1900 of the Botanic Garden and Domains, Sydney, New South Wales, by the director, Mr. J. H. Maiden, shows steady work in the improvement of the Gardens and the increased efficiency of the herbarium and library. The details are chiefly of local interest.

WE have received from the U.S. Department of Agriculture (Division of Botany) two interesting pamphlets (*Bulletins* Nos. 27 and 28): Seeds of Commercial Salt-bushes—*i.e.* species of Atriplex—grown as forage-plants in the arid regions of the West, by Mr. G. N. Collins; and The Chayote, a Tropical Vegetable, by Mr. O. F. Cook. The chayote or tayote, *Sechium edule*, a member of the Cucurbitaceæ, is better adapted for a tropical climate than most herbaceous plants. It has been grown from time immemorial by the aborigines of South America for its succulent fruit, but, like so many cultivated plants, is unknown in the wild state.

THE *Journal* of the College of Science of the Imperial University of Tokyo (vol. xv. part iii.) contains several interesting botanical articles, mostly in German; among the rest: On the organisms concerned in the fermentation of the Japanese spirit "awamori," by Mr. T. Inui, which is attributed mainly to a new species, *Aspergillus luchuensis*, accompanied also by *Aspergillus perniciosus*, sp.n., *Saccharomyces Awamori*, sp.n., and *S. anomalus*; on the transpiration of evergreen trees in winter, by Mr. S. Kusano; both transpiration and assimilation are continued through the winter in the climate of Tokyo; on the action of cupric sulphate on plants, by Mr. N. Hattori; and on the more important fibre-plants of Japan, by Mr. K. Saito.

THE first instalment of the second edition of Prof. van 't Hoff's "Vorlesungen über theoretische und physikalische Chemie," dealing with chemical dynamics, has been published by Messrs. F. Vieweg und Sohn, Brunswick. This is the part of the work which has been translated into French and English and already noticed in the review columns (vol. lix. pp. 458, 557, 1898).

THE Polygraphisches Institut of Zürich has just issued the first and second parts of a series of plates and descriptive text entitled "Arboretum Amazonicum." The author of this iconography is Dr. J. Huber, head of the botanical section of the Museum of Natural History and Ethnography at Para, and the work will be completed in ten parts. When the whole of the parts have been received a review of their contents will appear in these columns.

A SHORT address on the progress of physics during the nineteenth century, recently delivered before the St. Louis Academy of Sciences by Prof. F. E. Nipher, has been issued in the *Transactions* of the Society (vol. xi. No. 6). He remarks, in concluding his survey, "If the history of the last century has taught us anything, it has established the practical or commercial value of research in pure science. It is from such work that all of the great achievements have directly

come. And whenever any people forgets the source from which these great things have come, and allows engineering to supplant science, that people is on the way to the civilisation of China."

MESSRS. MARION AND CO. have just commenced the publication of reproductions of a fine series of photographs of "The Empire: its Cities, Palaces and Buildings." The views can be obtained in half-tone process prints or reproduced by collotype process. In the collection of pictures of "Famous Buildings of London," which forms one number of the series, we notice views of the Imperial Institute and the British Museum. The Natural History Museum deserves to be included, but there are few other fine buildings devoted to scientific research and education in London. Fine buildings do not necessarily make fine work, but they facilitate it and show in what regard the nation holds those who contribute to its scientific and industrial progress.

ABSTRACTS of the papers read before the Royal Society of New South Wales appear regularly among our reports of societies and academics. The volume of *Proceedings* containing the complete papers read before the Society in 1900 has now been received, and calls for a note of admiration. Among the subjects dealt with are the sun's motion in space, and the volumes of solids as related to transverse sections, by Mr. G. H. Knibbs; several papers on eucalyptus oils, by Mr. H. G. Smith; customs of Australian aborigines, by Mr. R. H. Mathews, Mr. W. J. Enright and Miss M. M. Everitt; the crystalline structure of some gold, silver and copper nuggets, by Prof. A. Liversidge, F.R.S.; and an experimental investigation of the strength of brickwork when subjected to compressive and transverse stresses, by Prof. W. H. Warren and Mr. S. H. Barraclough.

THE additions to the Zoological Society's Gardens during the past week include a South Albemarle Tortoise (*Testudo vicina*) from the Galapagos Islands, a Conical Eryx (*Eryx conicus*) from India, deposited; a Shag (*Phalacrocorax graculus*), European, purchased; an Axis Deer (*Cervus axis*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

NEW VARIABLE STARS.—The following newly-detected variables are announced in the *Astronomische Nachrichten* (Bd. 157, No. 3751):—

94, 1901, *Cygni*.—

A.G. Bonn (B.D. $+41°\cdot4114$)

$$\left.\begin{array}{l}\text{R.A.} = 21\text{h. } 17\text{m. } 42\text{s.}\\ \text{Decl.} = +41°\ 51'\cdot8\end{array}\right\}(1875\cdot0)$$

Herr Fr. Deichmuller states that there is a variation of about half a magnitude; the times are not sufficiently continuous to deduce a value of the period.

95, 1901, *Pegasi*.—Dr. T. D. Anderson announces variability in the star B.D. $+24°\cdot4462$, whose position is

$$\left.\begin{array}{l}\text{R.A.} = 21\text{h. } 37\text{m. } 56\text{s.}\cdot0\\ \text{Decl.} = +24°\ 20'\cdot6\end{array}\right\}(1855\cdot0)$$

The star is sometimes about 10 magnitude, but at intervals becomes much fainter.

96, 1901, *Cygni*.—Mr. Stanley Williams finds from photographs taken with a 4·4-inch portrait lens that variability exists in the star B.D. $+29°\cdot4231$.

$$\left.\begin{array}{l}\text{R.A.} = 20\text{h. } 49\text{m. } 2\text{s.}\cdot1\\ \text{Decl.} = +29°\ 51'\cdot8\end{array}\right\}(1855\cdot0).$$

The following variations are recorded:—

1901 Sept. 21 ... 10·81 mag.		1901 Nov. 1 ... 9·88 mag.
Oct. 7 ... 10·26 ,,		,, 3 ... 10·47 ,,
,, 14 ... 9·79 ,,		

These indicate a maximum of 9·7 magnitude on 1901 October 21. The star was invisible on plates taken on 1899 October 6 and 9, 1900 October 26, 27 and November 15, so that it must have been fainter than 12 magnitude. The period is at present uncertain.

BRIGHT METEOR OF DECEMBER 4.—A brilliant meteor was seen by several observers shortly after five o'clock in the evening of Wednesday in last week, December 4. Prof. J. P. O'Reilly, writing from Dublin, says:—"At 5h. 11m. p.m. this evening I saw in the south-eastern sky a brilliant meteor, which appeared at a point about 30° above the horizon and had a course about equal in length to the belt of Orion. The fore part was brilliant bluish-white, the after part red sparks. The direction of movement made with the horizon an angle of about 60° to 65°, the inclination of the line of movement being to the south. There were no stars visible by which I could more distinctly fix its position."

Mr. C. Waterer (Highfield, Northdown Avenue, Margate) and two friends saw the meteor while walking towards Kingsgate, near Margate. He remarks, "The trail remained visible to us all for some seconds. We were then looking west, and its direction was approximately from north to south. The time by my watch was 5.35 p.m."

"COMPANION TO THE OBSERVATORY," 1902.—This almost indispensable handbook for the practical observer has recently been issued for the coming year. The contents and arrangement are similar to those of previous issues. A small addition which will be useful to spectroscopists is the list of spectroscopic double stars, with their periods so far as is at present known.

THE VARIATIONS IN THE MAMMALIAN EYE.[1]

DR. LINDSAY JOHNSON'S work, in the investigation of the deep anatomy of the mammalian eye as displayed by the ophthalmoscope, has been of a very extensive and persevering, not to say of a very adventurous character; and the volume before us, containing his contribution on the subject to the *Transactions* of the Royal Society, represents no more than a fraction of the material which he has collected, and which he intends, we understand, one day to publish. Not the least interesting part of it will be that which will deal with his methods, with the perils occasionally attendant upon them, and with the contrivances by means of which a living lion and a living whale were compelled to submit themselves to ophthalmoscopic examination. Mirror in hand, Dr. Johnson has not only visited the zoological gardens of many countries, but also the native haunts of many wild creatures; and in the book before us some of his discoveries are displayed in twenty-six plates, containing fifty coloured drawings of eyegrounds, beautifully finished and exquisitely reproduced in chromo-lithography, and in three plates with drawings in black and white, showing variations in the forms of persistent hyaloid artery, rudimentary forms of pecten, and different types of the appendages which are found on the pupillary margins of many of the ungulata.

The general result of Dr. Johnson's observations is to show the existence among mammalia of very wide differences in two respects; first, as regards the vascular supply of the optic nerve and retina; secondly, as regards the presence, coloration and pigmentation of the tapetum.

With regard to the first of these, it may be said that the general type presented by the human eye, that is, the presence of a central artery and vein of the retina, finding entrance and exit among the fibres of the optic nerve, and constituting a practically closed and complete retinal circulation, is more or less preserved in monkeys, lemurs, the carnivora, some of the ungulata, some of the rodentia, and some marsupialia, but is either absent or concealed by tapetum in the Australian fruit-bat, the Indian rhinoceros, Burchell's zebra, the American tapir, the African elephant, the Canadian beaver, the chinchilla, the guinea-pig, the Central American agouti, the Brazilian porcupine, the hairy armadillo, the wombat, the squirrel-like phalanger and the echidna; while among these latter animals there are great differences in the blood-supply of the optic disc itself, which in some of them, as in the Indian rhinoceros and the hairy armadillo, is of a dead white like the whiteness of atrophy in the human subject; while in others, as the zebra, it is abundantly vascular, and is surrounded by a radiation of small

[1] "Contributions to the Comparative Anatomy of the Mammalian Eye, chiefly based on Ophthalmoscopic Examination." By George Lindsay Johnson, M.D., F.R.C.S. From the *Philosophical Transactions* of the Royal Society of London for 1901. Pp. 82, with 26 plates in colour and 4 in black and white. Price 21s.

vessels extending a short distance from its periphery. In many animals the optic disc is deeply excavated up to its margins, and resembles that of chronic glaucoma in the human subject, a state of which the best examples are furnished by the seal, the serval, and the red and white flying-squirrel. The condition presented by the rabbit, in which some of the fibres of the optic nerve carry their sheaths through the lamina cribrosa to form an opaque patch on the retina, is met with in many other animals, but with much variety in the depth and distribution of the opacity.

The coloration of the tapetum varies greatly in different animals; and Dr. Johnson calls particular attention to his drawing of the eye of Monteiro's galago, in which the general yellow of the central part of the fundus is surrounded by a zone of pigmentation precisely resembling what is called "pigmentary retinitis" in the human subject. Dr. Johnson inclines to the belief that the affection so described is not really a disease, but rather a reversion to a type of structure which is the rule in night-seeing animals.

It is impossible to withhold a tribute of admiration from the perseverance with which Dr. Johnson has conducted his researches, or from the beauty of the drawings in which the results of his observations are displayed; but it is for the moment necessary to retain a suspended judgment with regard to the value of his work. As an observer he stands alone; and the drawings which he has made, notwithstanding their great and obvious merit, are as yet mere personal records, liable, it may be, to some disturbing influence from a personal equation. It is much to be regretted that photography has not been made available for taking pictures of the eyeground from which this element of uncertainty would be removed. Even if this were done, it would still be necessary to determine, by more extended portraiture, whether the conditions described are normal ones or subject to variation in individuals. We cordially welcome Dr. Johnson as a pioneer, and we feel sure that he will fully appreciate the necessity for caution in accepting his conclusions.

THE COAL-TAR COLOUR INDUSTRY IN GERMANY AND ENGLAND.

WITH the object of ascertaining our present and future prospects in the chemical trade of the world, Mr. A. G. Green, in a paper read before the section of chemistry of the British Association, at this year's meeting, described the relative progress of the coal-tar industry in England and Germany during the past fifteen years. The council decided to print the paper *in extenso*, and the subjoined particulars extracted from it convey an idea of what England has lost by the neglect of the scientific foundations of an industry. The paper may be regarded as a sequel to one by Prof. Meldola published in NATURE fifteen years ago (vol. xxxiv. p. 324), when the position of the industry in Germany and England was described, and a warning was given to British manufacturers.

The exports of coal-tar colours manufactured in England have fallen from 530,000*l.* in 1890 to 366,500*l.* in 1899. Comparing these figures with the rapidly increasing export trade of Germany, it is seen that whereas formerly the English export trade in artificial colours was about one-quarter that of Germany, it does not now amount to a tenth part. It is therefore only too apparent that we have had but little share in the great increase which this industry has experienced during the past fifteen years, and that we have not even been able to supply the expansion in our own requirements. In order to ascertain what proportion of our own needs we at present furnish, I am able to lay before you the following interesting figures, which have been kindly supplied me by the Bradford Dyers' Association and the British Cotton and Wool Dyers' Association, who together form a very large proportion of the entire dyeing trade:—

Colouring Matters used by Bradford Dyers' Association.

English, 10 per cent.; German, 80 per cent.; Swiss, 6 per cent.; French, 4 per cent.

Colouring Matters used by British Cotton and Wool Dyers' Association.

Aniline Colours.—English, 22 per cent.; foreign, 78 per cent.

Alizarine Colours.—English, 1·65 per cent.; foreign, 98·35 per cent.

The *English Sewing Cotton Company* have also very kindly supplied me with a detailed analysis of their consumption, from which it appears that out of a total of sixty tons of colouring matters and other dyeing materials derived from coal tar, only 9 per cent. were of English manufacture.

The following table of statistics of the six largest German firms gives a fair picture of the present dimensions of the industry in that country (*vide* next page).

The joint capital of these six firms amounts to at least $2\frac{1}{2}$ millions. They employ together about 500 chemists, 350 engineers and other technologists, 1360 business managers, clerks, travellers, &c., and more than 18,000 workpeople. Compared with such figures as these the English colour manufacture assumes insignificant proportions. The total capital invested in the coal-tar colour trade in England probably does not exceed 500,000*l.*, the total number of chemists employed cannot be more than thirty or forty, and the number of workmen engaged in the manufacture does not amount to more than a thousand.

A similar relative proportion is maintained in the number of patents for new colouring matters and other coal-tar products taken by the English and German firms, as is shown by the following table:—

Comparison of Number of Completed English Patents for Coal-tar Products taken during 1886–1900 by six largest English and six largest German Firms.

German Firms.	
Badische Aniline Works	179
Meister, Lucius, & Brüning	231

Brooke, Simpson, and Spiller	7
Clayton Aniline Co.	21
Levinstein	19
Read, Holliday, & Co.	28
Claus & Ree	9
W. G. Thompson	2
Total of six English firms	86

Nor does the potential loss which we have sustained by our inability to take advantage of a growing industry represent the sum total of our losses. The new colouring matters, made almost exclusively in Germany, have in many cases been introduced as substitutes for natural products, which were staple articles of English commerce. Madder and cochineal have been replaced by alizarine and azo-scarlets, the employment of many dyewoods has greatly decreased, whilst at the present moment logwood and indigo are seriously threatened. Regarding the indigo question so much has been written that I do not propose to occupy space in its further discussion, but will only point out that the complete capture of the indigo market by the synthetic product, which would mean a loss to our Indian dependencies of 3,000,000*l.* a year, is regarded by the Badische Company as so absolutely certain that, having already invested nearly a million pounds in the enterprise, they are at present issuing 750,000*l.* of new debenture capital to provide funds to extend their plant for this purpose! In the last annual report of the company they say: "As regards plant indigo, the directors are prepared and determined to meet this competition in all its possible variations in value. Much strange matter has been published in India as to improvements in the cultivation and preparation of natural indigo, but the illusions of the planters and indigo dealers are destined to be dispelled before facts, which, although they are not known to them, will make themselves more felt the larger the production of artificial indigo becomes."

Besides the loss of material wealth which the neglect of the coal-tar trade has involved to the country, there is yet another aspect of the question which is even of more importance than the commercial one. There can be no question that the growth in Germany of a highly scientific industry of large and far-reaching proportions has had an enormous effect in encouraging and stimulating scientific culture and scientific research in *all*

Position of the Six Largest Colour Works in Germany in Year 1900.

branches of knowledge. It has reacted with beneficial effect upon the universities, and has tended to promote scientific thought throughout the land. By its demonstration of the practical importance of purely theoretical conceptions it has had a far-reaching effect on the intellectual life of the nation. How much such a scientific revival is wanted in our country the social and economic history of the past ten years abundantly testifies.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—An interesting ceremony took place on Saturday last, when a portrait of Prof. G. D. Liveing, painted by Sir John Reid, president of the Royal Scottish Academy, was presented to St. John's College as a mark of recognition of Prof. Liveing's services to science. The portrait was provided by subscription, and the funds obtained will also enable a bronze bust of Prof. Liveing to be placed in the Chemical Laboratory at Cambridge. The Vice-Chancellor (Dr. Ward, Master of Peterhouse) presided at the meeting of subscribers, and the attendance included the Lord Lieutenant, Sir John Gorst, Sir Richard Jebb, the Masters of Trinity, St. John's, Clare, Jesus, Christ's, and Downing, Profs. Sir George Stokes, E. C. Clark, J. Dewar, W. J. Lewis, A. R. Forsyth, J. Westlake, J. J. Thomson, J. A. Ewing, W. W. Skeat and J. S. Reid, besides many other resident members of the Senate.

PRINCIPAL RÜCKER, F.R.S., will distribute the prizes and certificates to students of the South-Western Polytechnic, Chelsea, to-morrow evening, December 13. The chair will be taken by Mr. Sidney Webb.

PROF. EDGAR CROOKSHANK, who lately resigned the active duties of the chair of comparative pathology and bacteriology in King's College, London, which he occupied for fifteen years, has had the title of Emeritus Professor conferred upon him by the Council in consideration of his long and brilliant services.

THE St. Petersburg correspondent of the *Times* states that the Minister of Public Instruction has made a decree expelling all the first-year students at the Kharkoff Veterinary Institute for insulting the professor of chemistry at that college. The reason for this action on the part of the Minister is the fact that on November 28 the first-year students sent a signed request to the professor of chemistry that he should resign his chair on the ground that his teaching was unsystematic and obscure. The decree adds that the professorial staff were agreed that the charge against their colleague was without foundation.

THE *British Medical Journal* states that the municipality of Hamburg has adopted a scheme by which all the scientific institutions of the city are to be grouped together into a university. The directors of these institutes and the lecturers, who have the title of professors, will form the professorial college, which every year will elect its own president. It will also be the duty of the college every year to draw up a programme of lectures and practical courses. The programme for the current winter semester includes courses by 117 lecturers. This movement is a step towards the foundation of a fully-equipped university in Hamburg, a project which has long been under consideration.

AFTER a meeting of the U.S. Cabinet on Tuesday it was stated that the President had received a communication from Mr. Carnegie on the subject of the creation of a fund for the extension of higher education. The amount said to have been offered is ten million dollars. It is understood (says the *Times* correspondent at Washington) that the proposal does not involve the establishment of university buildings at Washington, but that it is intended rather to place a fund in the hands of Government trustees, from which the expenses of deserving students may be paid for the encouragement of original research at home or abroad. It is believed that the proposal has not yet taken concrete form, except as regards its general terms and the amount of the gift. The President will consult with members of Congress with regard to the proposed gift before making its terms public.

MR. HANBURY, President of the Board of Agriculture, distributed the prizes at the Derby Municipal Technical College last week, and gave an address upon some aspects of technical education. In the course of his address he remarked that he believed that partly where the United States and Germany had the advantage of England was not in the technical education of their working classes, but among the great leaders of commerce and industry. Commercial education must spread from the top to the bottom. They wanted to have commercial instincts and business capacity instilled into their leading commercial men, even up to the universities themselves. England was far behind America in that respect. Twenty years ago there was only one college of the kind to which he referred in the States, and that was in Pennsylvania; now there were at least nine or ten universities in the Union which were giving that commercial education to the leaders of the country's commerce and industry. It was, unfortunately, the fact that they were lacking in a good system of secondary education. He hoped something would be done in the matter in the next session of Parliament. The foundation for the work of technical schools was a good, sound education, which could only be obtained in the secondary schools. This was the reason why at the present moment they did not find in technical schools those advanced students and day scholars which he hoped, under the new system, they would find flocking into them.

THE movement in favour of reformed methods of mathematical teaching can be assisted by discussions at provincial scientific societies and university centres. A discussion of this kind took place at the meeting of the Royal Glasgow Philosophical Society, held on December 6, Prof. Gray being in the chair, when the subject of the teaching of mathematics to engineers was opened by Prof. Barr. It was remarked by him that the engineer uses mathematics as a tool, and it is not essential for the man who uses tools to manufacture them. He did

not think it necessary that strict mathematical proofs should be given for everything. An engineer learned physical constants, and physical data might be taken for granted. He believed that the education of the engineer in mathematics would gain and not lose if instead of strict proof there was more of illustration. Prof. Barr gave the calculus an important position, but expressed his desire for the portable formulæ advocated by Prof. Perry. Dr. H. S. Carslaw, in the course of some remarks, said if teachers in schools would anticipate the teachers in the colleges by using graphical methods they would not hear mathematics spoken of as killing thought and destroying education. At present Euclid is given far too prominent a position in school work, with the result that algebra and trigonometry suffer. Prof. G. A. Gibson expressed general agreement with the views of Prof. Barr. He would not, however, insist too much on doing away with logical demonstration. The foundation for the teaching of mathematics should be laid at school, and he complained that two years of a schoolboy's life were worse than wasted by the enormous amount of rules which he had to commit to memory, which were of no intellectual interest and which he was almost certain to forget.

THE Education Committee of the General Medical Council presented a second report on the steps to be taken for the improvement of preliminary examinations at the meeting of the Council last week. Sir John Batty Tuke, chairman of the Committee, in presenting the report explained that in November, 1898, the Education Committee was asked to report when, in its opinion, it would be practicable to raise preliminary examination to the senior and higher standards. In June, 1899, the Committee reported, after consultation with a large number of educational authorities, that it would be better if educational experts were appointed to review the circumstances of all examinations. Experts were appointed, and in December, 1899, the Committee submitted a report, along with a report of the experts, who held that it was impossible to raise the standard to the senior or higher grade in the present condition of secondary education in Great Britain. Thereupon the experts were asked to state reasons for the belief. In March, 1900, they gave these reasons, and the Committee was then enabled to work upon certain fixed principles. The principal difficulty met with was how to produce a rise in the character of examinations in reality, a real *bonâ-fide* rise. It was easy to make an examination look more serious on paper than it really was. The Committee had not asked for this to be done, but had made representations to the various examining bodies, asking them to raise the standard of the pass-marks rather than increase the difficulty of an examination. Feeling that the Council had the true interests of education at heart, the various examining bodies had met the Committee in the most conciliatory spirit and had, wherever necessary, provided examinations in order to bring about a common good. The Committee expressed the opinion that it would not be practicable to raise the standard of the examinations until the state of secondary education in the country was in a less chaotic condition than it is now. The responsibility lay with the country, and it was sincerely to be hoped that the Government during the next session would bring forward a strong measure by which this important object might be attained. After some discussion, the Council adopted the motion "That the report of the Education Committee on the steps taken for the improvement of preliminary examinations be approved."

SCIENTIFIC SERIAL.

Bulletin of the American Mathematical Society, November.—On wronskians of functions of a real variable, by Prof. Bôcher, has for its object the settling certain questions connected with the subject so as to clear the way for further investigations—such as whether the roots of wronskians of sets of linearly independent solutions can have an infinite number of roots in a given interval, and also the question to what extent the theory of the adjoint (adjungirte) differential equation remains valid when the coefficients of the differential equation are not assumed to be analytic but merely continuous functions. To do this he considers the slightly more general subject of linear families of which the solutions of a homogeneous linear differential equation form a special case. The paper was communicated at the August meeting of the Society, as also was the following, on the configurations of the 27 lines on a cubic surface and the 28 bitangents to a quartic curve, by Prof. L. E. Dickson. After determining four systems of simple groups in an arbitrary domain of rationality which include the four systems of simple continuous groups of Lie, the author was led to consider the analogous problem for the five isolated simple continuous groups of 14, 52, 78, 133 and 248 parameters. The groups of 78 and 133 parameters are related to certain interesting forms of the third and fourth degrees respectively (Cartan's thèses), and these suggest certain forms discussed in the paper.—Dr. G. A. Miller gives an account of the mathematical work done at the fiftieth annual general meeting of the American Association for the Advancement of Science. There are given the titles, with abstracts, of twenty-five papers.—Prof. J. S. Ames reviews "Die partiellen Differentialgleichungen der mathematischen Physik" (nach Riemann's Vorlesungen in vierter Auflage neu bearbeitet von Heinrich Weber, erster bd. 1900, zweiter bd. 1901).—Amongst the notes are included the Cambridge mathematical courses for the current academic year.—New publications as usual.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 21.—"On the Properties of the Arterial and Venous Walls." By John A. MacWilliam, M.D., Regius Professor of Physiology in the University of Aberdeen. Communicated by Sir Michael Foster, K.C.B., Sec. R.S.

November 28.—"A Comparative Study of the Spectra, Densities and Melting Points of some Groups of Elements, and of the Relation of Properties to Atomic Mass." By Hugh Ramage, B.A., A.R.C.Sc.I., St. John's College, Cambridge. Communicated by Prof. Liveing, F.R.S.

It has been usual for investigators to rest satisfied when the properties of the elements were shown to be "a periodic function of the atomic mass." Diagrams drawn by the method employed in this paper will show in what degree the properties vary with the atomic mass, and will make it easier to establish the exact quantitative relations.

The work and results presented by the author make it clearer that the properties of the elements are fundamentally due to the structure, as revealed by their spectra, of the atoms rather than to the quantity of matter in them. It is inconceivable, for instance, that the change from calcium to strontium proceeded through the intermediate elements when we consider that the strontium molecules must have a similar structure to those of calcium. This structure is so simple that the fundamental (Bunsen flame) spectrum of each of these elements contains only one line attributed to the element. The anomaly, according to Mendeléeff's law, in the atomic masses of tellurium and iodine is further evidence of this. The properties of these elements may have nothing whatever to do with each other. They are, however, closely related to and in correct order with those of the elements of their respective groups. The genesis was not in the direction of tellurium to iodine, but from, or perhaps through, oxygen and fluorine respectively. So also is this the case with the other groups.

It is more probable that in the genesis of the elements the properties of certain fundamental matter are modified by successive additions of matter to them, or by causes of which this is to us the apparent result. The regularity in the changes in the properties of lithium, beryllium, boron and carbon, as seen in the diagrams, is very remarkable. It is, furthermore, very suggestive, for the changes in properties are approximately proportional to the quantity of matter in the atom in excess of a constant quantity (which is about 6), as if it were the same matter that is added in each case.

Geological Society, November 20.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—Dr. Vaughan Cornish exhibited photographs of waves and ripples in water, cloud, sand and snow.—Notes on the Genus Lichas, by Mr. F. R. C. Reed. The Lichadidæ are divided into two great groups: (1) that with a pair of bi-composite lateral lobes to the glabella and a more or less definite fourth pair of lateral lobes; and (2) a group with a pair of tri-composite lateral lobes, through the fusion of the fourth pair with the bi-composite pair of the preceding group. Names are proposed for each group, and also, where necessary, for the eight sections, of subgeneric value, into which each group is subdivided. The

paper closes with a list of the British members of the family Lichadidæ, to show their distribution among the groups and sections.—Some remarks on the meteorological conditions of the Pleistocene epoch, by Dr. Nils Ekholm. The opinion of the author on this subject differs in some important respects from that of Mr. Harmer. He considers the subject under two heads: (1) What are the meteorological conditions necessary and sufficient to produce a permanent ice-sheet such as that of the Great Ice-Age? (2) What will be the influence of such glaciation on the meteorological conditions, especially on the cyclones and anticyclones, of the ice-covered land and on its neighbourhood? The snow-line does not correspond with the mean annual isotherm of 32°, for Verchojansk in Siberia is not glaciated, whereas the southern point of Greenland is. The former has a winter anticyclone, while the latter is traversed by the central or northern part of cyclones during the whole year. The area of Pleistocene glaciation in America and Europe coincides with the areas now traversed by the most regularly frequented storm-tracks. There seems to have been about the same difference between the mean annual temperatures of Europe and North America in the Great Ice-Age as now, and it is generally agreed that a lowering of the present snow-line by 1000 metres would give rise to a similar Ice-Age. The hypothesis that a glaciation of North America would raise the temperature of Europe, and *vice versâ*, seems to the author physically untenable. The positions and movements of anticyclones are not generally ruled by the ground temperature in our latitudes: they are in most cases eddies formed by the air-circulation in general, and in this the greater area and receipt of heat by the equatorial regions must always be a preponderating factor. The author considers that the influence of the Glacial Period on atmospheric circulation would probably be similar to that of a cold winter nowadays. The cyclones would be gradually deviated into a more and more southerly track, while an anticyclone would be formed in the north, not, however, a stationary one, but travelling like a cyclone, only more slowly and irregularly. The summer must have been cold and stormy, with frequent fogs, somewhat like that of Cape Horn or Kerguelen Island at the present day. The author considers that Mr. Harmer underrates the effect of insolation and overrates that of the winds. "The temperature of the summer only is essential for the phenomenon of glaciation."—On the origin of certain concretions in the Lower Coal-Measures, by Mr. H. B. Stocks. In certain of the Lower Coal-Measures of Lancashire and Yorkshire and in the "hard-bed coal," peculiar concretions known as "coal-balls" occur, which have a considerable interest because they contain well-preserved plant-remains. The author's analysis shows that they consist mainly of calcium-carbonate and iron-pyrites, in varying proportions. Carbonate of lime appears to have been introduced by osmosis through the cell-walls; and that it was introduced in small quantity and under exceptional circumstances appears to be proved by the comparative rarity of the concretions and their presence in this seam of coal only. During the decay of the vegetable matter of which coal is formed, in contact probably also with animal matter, some of the organic matter would pass into solution in water, causing the absorption of the oxygen in solution; the result of this is that further decay would take place under anaërobic conditions. This, occurring in water containing sulphates, would give rise to sulphuretted hydrogen and mud blackened by the presence of ferrous sulphide, while carbonates would also be produced. Experiments were tried (1) on the precipitation of carbonate of lime under varying conditions (in presence of organic matter, &c.); (2) on the action of salts of lime and of iron on wood; and (3) on the action of bacteria on solutions containing calcium-sulphate in solution and ferric oxide in the deposit. In the first series carbonate of lime was deposited in spheres; in the second it was found that iron-salts are preservatives but lime-salts are not; and in the third, black mud largely consisting of ferrous sulphide was produced, while the calcium-sulphate was converted into carbonate. It is considered that these experiments explain the origin of the "coal-balls."

Linnean Society, November 21.—Prof. S. H. Vines, F.R.S., president, in the chair.—Dr. A. B. Rendle showed specimens of *Rubus australis*, Forster, the New Zealand "lawyer-vine," which had been sent by Mr. F. W. Burbidge from the Trinity College Botanic Gardens, Dublin. The specimens, which comprised three forms, furnished a striking example of variability within the range of a single species. One, the leafy form, bore leaves with three large leaflets somewhat prickly on the stalks and midrib, recalling our native blackberry. In an intermediate form the leaflets were much reduced in size, while the stalks were longer and much more prickly. In a third the flat leaf-surface had completely disappeared, the leaves now consisting of an elongated stalk bearing long naked midribs, beset, like the leaf-stalks and the stem, with strong, short, recurving prickles, by means of which the plant climbs over surrounding vegetation. Mr. Burbidge states that the three forms are from three distinct plants, reared from seeds sent from New Zealand; they are said to be permanent under cultivation.—The president gave some account of his investigation of the proteolytic enzyme of Nepenthes. He began by pointing out that in the higher animals there are two distinct proteolytic enzymes: (1) pepsin, secreted by the stomach; (2) trypsin, secreted by the pancreas. The action of pepsin upon the more complex proteids (albumin, fibrin, &c.) is to convert them by hydrolysis into simpler proteids known as peptones; whereas the action of trypsin is not only to convert these proteids into peptones, but, further, to decompose the peptones into non-proteid nitrogenous substances, such as leucin, tyrosin, &c. Among these final products of tryptic digestion there is a substance termed tryptophan, which has the property of giving a pink or violet colour on the addition of chlorine-water. Hence this colour-reaction may be used as a means of determining the nature of the digestion to which any proteid may have been submitted. As the result of previous researches upon the nature of the digestion effected by the enzyme of Nepenthes, the president had come to the conclusion that it was not peptic, as had been supposed, but essentially tryptic. This conclusion has recently been called in question by Clautriau (Acad. Roy. de Belgique, 1900), who reasserts the peptic character of the enzyme. By means of the tryptophan-reaction, which is readily given by the products of a Nepenthes digestion, the president has been able to establish the correctness of the view that the enzyme is tryptic. The tryptophan-reaction has also been found to be given by a number of extracts of plants which are known to contain a proteolytic enzyme; for instance, pineapple-juice, papaïn, figs, germinating bean-seeds, &c. It seems probable, therefore, that proteolytic digestion in plants is always tryptic—that there is, in fact, no peptic enzyme in plants. But there is this peculiarity about the trypsin of plants, that it has to work in an acid medium.—A paper by Mr. T. F. Cheeseman on the flora of Rarotonga was read on his behalf by Dr. O. Stapf, who also showed some of the more interesting plants collected on the island.

Entomological Society, November 20.—Mr. G. H. Verrall, vice-president, in the chair.—Mr. A. H. Jones exhibited various Lepidoptera from the Cevennes, including a series of *Lycaena dolus*, var. *vittata*, *L. damon*, *L. meleager*, *Melanargia iapygia*, var. *cleanthe*, and *M. galatea ab. leucomelas*: also a dark form of *Thais cerisyi* bred from a pupa received from Armenia. He also exhibited a specimen of *Vanessa antiopa* taken this year at Eltham, and two specimens of *Cerastes erythrocephala* bred from ova laid by parent moth captured at sallows near Canterbury.—Mr. H. Rowland-Brown exhibited a remarkable var. of *Melitaea didyma*, taken at Chateau de la Câze, Tarn, in which the black markings of the under wings were almost entirely absent, and a series of *Lycaena dolus*, var. *vittata*, from the Cevennes, with *L. admetus*, var. *rippertii*, from Digne, showing the remarkable affinity of the two species, which, however, were never found on the same ground or in the same localities while collecting.—Dr. Chapman exhibited butterflies taken by himself and Mr. G. C. Champion in the Sierra Albarracin, Spain, last July, practically the same district as that traversed and described by Mrs. Nicholl in her paper in the Society's Transactions for 1897, and not many new butterflies were added to Mrs. Nicholl's list. *Z. quercus* was taken at Tragacete. *Augiades sylvanus* was taken both at Albarracin and Tragacete. *Adopaea actaeon* was met with a Cuenca (Castile), while *Adopaea linea* seemed to be more abundant than *A. lineola* at all stations. *L. hylas* and its variety *nivescens* were found on the same ground. The common form of *L. corydon* seemed to be *corydonius* or near that variety, while the very large pale form *hispana* was the commonest at Albarracin, where the *corydonius* form was rare.—Mr. L. B. Prout exhibited and commented upon a number of Geometridæ also taken by Dr. Chapman and Mr. Champion in Spain.—Mr. F. Merrifield exhibited specimens of *Pieris rapae* and *Pieris ergane* from

Dalmatia, showing that the two species are extremely difficult to separate, even if they are not identical.—Mr. C. P. Pickett exhibited varieties of *Argynnis paphia* and *A. aglaia* from the New Forest.—Mr. C. J. Watkins sent for exhibition microphotographs of the larva in its case and the perfect insect of an *Oxyethira*, one of the *Hydroptilidae*, a family of *Micro-Trichoptera;* these had been taken by Mr. Mearns, of Aberdeen. Also a drawing made by himself under the microscope of a larva (in its case) of the same genus.

Royal Microscopical Society, November 20.—Mr. Wm. Carruthers, F.R.S., president, in the chair.—Four microscopes of great interest were presented to the Society. Descriptions of three of these prepared by Mr. Nelson were read. With regard to one made by Powell and Lealand in 1848, Mr. Nelson writes:—This form was the first instance in which the microscope was hung in a tripod, and it was also the first where the fine adjustment moved a nose-piece by means of a lever inside a bar movement, and this specimen must have been about the last microscope made with the fine-adjustment screw at the side of the bar, for it was in this year, 1848, that the screw was placed vertically above the lever, where it has remained ever since. Other features were referred to, and Mr. Nelson characterised it as historically an important and not very common form of Powell and Lealand's microscope. The next microscope described was an old one made by Hugh Powell, certainly before 1841, as in that year Mr. Lealand joined the firm, and his name would have been coupled with that of Powell, and the presence of a substage condenser prevents it being dated earlier than 1839. An important feature is the stage, which has an arrangement for focussing by means of three wedges, moved by a micrometer screw. The stage has also a transverse micrometer movement for the measurement of objects. The third microscope was made by John Cuff. The date of its introduction was 1744 and it was called "A New Constructed Double Microscope." After the John Marshall microscope this is historically one of the most important instruments in the Society's collection. The other microscope presented was made by Plössl and Cie, Vienna, and has already been described in the *Journal* of the Society.—Messrs. R. and J. Beck exhibited a new pattern microscope embodying several new features. The substage was fitted with coarse and fine adjustments and means of throwing out the condenser while it was in focus. The stage, 5 inches diameter, was rotating and graduated on the periphery, with a removable mechanical stage graduated as a finder. The body was very short, fitted with double draw tube, which allowed the body to be extended to 11½ inches. The body was fitted with Ashe's new double fine adjustment.—Mr. Conrad Beck gave an exhibition of antipoints, and said they were extremely difficult to show on account of the trouble there was in obtaining points of light sufficiently small and bright, and it was only possible to obtain faint images with so much diffused light as there was in that room. There were six microscopes, all having ½-inch objectives, and the points of light in the first two cases were produced by minute apertures in tinfoil, in the others the light was reflected from small mercury globules. With the first microscope a point of light was viewed with ½-inch objective of ordinary aperture and showed a *point* of light surrounded with faint diffraction circles. With the second microscope a similar point of light was viewed with a ½-inch objective of very small aperture and showed a *disc* of light and diffraction rings. The other microscopes showed the effects produced by placing various stops behind the objectives, and also by viewing the point of light through a grating which extended the whole aperture of the objective. Mr. J. W. Gordon said he had listened with great interest to Mr. Beck's explanation of the demonstration and was anxious to see the examples, and no doubt the experiments would demonstrate the existence and appearance of the antipoint in each case; but there was another and equally important image which he would like to see and that was the antipoint which was formed in the eye, and he hoped some day Mr. Beck would be able to give a demonstration of this.—A paper on stereomicrography, by Prof. G. P. Girdwood, of M'Gill College, Montreal, was read by the secretary. Prof. Girdwood's method of obtaining stereo-microphotographs was by placing the slide or object in a tilting frame attached to the stage of the microscope. The frame with the object was tilted to one side to the proper angle and a photograph was taken; the frame was then tilted to an equal amount in the opposite direction and another photograph was taken. Prints from the negatives were then mounted in the usual way to form stereoscopic pictures. The paper was illustrated by a diagram on the blackboard, and a specimen of the stereoscopic photographs, placed in a stereoscope, was passed round the room.

DUBLIN.

Royal Dublin Society, November 20.—Prof. W. Noel Hartley, F.R.S., in the chair.—Prof. T. Johnson gave an account of the results of field experiments he had conducted during the past two years in the west and north-west of Ireland in the prevention of "smut" (*Ustilago avenae*, Jens.) in oats. The fungicides used were potassium sulphide (weak and strong solution), copper sulphate, formalin alone, and followed by ammonia, and the new fungicide "sar" (essentially sodium sulphide) recommended by the United States Department of Agriculture. The latter was found by the author to be the most efficient remedy.—Dr. F. T. Trouton, F.R.S., described some experiments made by him at the request of the late Prof. G. F. FitzGerald, in which it was sought to detect an effect depending on the relative motion of the earth and ether. A charged condenser placed with its plates edgeways to its motion through the ether should possess a magnetic field. The question to be investigated was the source of the energy for this field. FitzGerald's supposition was that at the moment of charging the condenser should experience an impulse in the direction opposed to its motion and on discharging in the direction of motion. A condenser was therefore delicately suspended at the end of a cross-arm with a balance weight at the other end held by a torsion wire. The arm stood north and south and it was sought to detect at 12 o'clock if there was an impulse acting on the condenser when it was charged and discharged. This was effected synchronously with the period of the apparatus by a clock. No effect was observed though the calculated effect was long within the range of delicacy. FitzGerald had anticipated the possibility of a negative result being obtained through the same cause as was suggested by him and Lorenz to account for the negative results obtained by Michelson and Morley in their interference experiments, namely, the alteration in the weight of matter with direction of motion through the ether. The alteration thereby produced in the electrostatic energy would in this way provide the necessary energy for the magnetic field. The author pointed out that if it be thought that the energy from the magnetic field is attributable to the charging battery, it follows that charge condensers tend to set themselves at right-angles to the earth's motion through space. For on this hypothesis a condenser charged in the latter position and rotated must have work done on it to energise the magnetic field thereby produced. Thus, in this case it would be a couple that should be looked for and not a directed impulse. He proposed to test this by delicately suspending a light condenser charged to a high voltage. It was also pointed out that if this were true it would be possible to obtain continuous rotation thereby, and thus to construct a machine to utilise the vast stores of energy in the earth's motion through space.—Prof. W. N. Hartley read a paper on haze, dry fog and hail. Last February a paper by the author, conjointly with Mr. Hugh Ramage, was communicated to the Royal Society, on the mineral constituents of dust and soot from various sources. Solid particles brought down by rain, hail, snow and sleet were submitted to analysis by means of the spectrograph, an instrument by which the composition of very minute quantities of substances is ascertained by photographing their spectra. For comparison with these different kinds of dust, and to ascertain their origin, the spectra of various other kinds of matter were photographed, for instance, meteorites, volcanic dust, soot, and flue dust from different chemical works and iron smelting furnaces. The result of this examination showed that the origin of the dust could in certain cases be ascertained from its composition. In the present paper the author described the discharge of vast volumes of dust and fume at very high temperatures into the upper atmosphere which he had observed in furnace operations at various metallurgical works in England and Wales. He had arrived at the conclusion that such material as had fallen in Ireland was the product of the industrial centres of South Wales or South Staffordshire and possibly the pottery district of North Staffordshire. In certain cases it may have come from the centre of the alkali manufactures about Widnes in Lancashire and Runcorn in Cheshire. There is also a likelihood that the neighbourhood of Glasgow contributes a good deal, as, for instance, on the occasion in 1898, when with a slight north-easterly wind black rain fell in Ireland over an area of 500 square miles.

EDINBURGH.

Royal Society, November 18.—Lord M'Laren in the chair.—In a paper on the equilibrium of stellar atmospheres, Dr. Halm applied the principles of thermodynamics to the problem of the convective equilibrium of masses of gas such as constitute the atmospheres of celestial bodies. A theoretic formula was established from which, under given conditions of boundary temperatures, the minimum temperature consistent with convective equilibrium could be calculated. In the case of our own atmosphere, it appeared that thermostatic equilibrium could exist when the temperature was lower than 45° or 50° F.; but that at higher temperatures the equilibrium must be convective. In the case of the sun, however, it was found that even with very extreme assumptions as to the temperature of the uppermost layers of the atmosphere there could be a layer of only inappreciable thickness in which thermostatic equilibrium was maintained. The equilibrium was practically convective throughout the whole mass, a result in full accordance with the facts of observation. The theory also gave a formula for calculating the height of a stellar atmosphere. When applied to the case of the sun the height of the hydrogen atmosphere came out much smaller than the observed height—a discrepancy which may be removed by the assumption that there is dissociation going on, so that the specific heat of hydrogen greatly increases at the higher temperatures. A full discussion of these and related results was held over for a subsequent paper.—Dr. Peddie read a paper on quaternion binaries, an extension of quaternions giving an eight-element system applicable to ordinary space. In this system vectors are regarded as translators only. A special operator R transforms them into rotors, and a second application of the same operator transforms the rotor into a translator. The system is formally Hamilton's, with the removal of the restriction that vectors shall act as translators in addition and as rotors in multiplication. The quantities ijk being unit rectangular vectors, the fundamental equations may be written

$$\mathrm{R}ij = k,\ \mathrm{R}jk = i,\ \mathrm{R}ki = j,$$
$$i^2 = j^2 = k^2 = -1,\ \mathrm{R}^2 = +1.$$

The fundamental properties of the quaternion binary $\mathrm{B} = q + \mathrm{R}r$, where q and r are quaternions, were investigated, the applications being restricted to the theory of screws, in particular to screws upon a cylindroid.—Prof. Chrystal, in a further note on Miller's trisectrix, pointed out its relation to the quartic trisectrix, and exhibited a seven-bar linkage for tracing all varieties of limacon. It was built up of a rhombus guided in its motions by two contraparallelograms.

PARIS.

Academy of Sciences, December 2.—M. Fouqué in the chair.—On the essential singularities of differential equations, by M. Paul Painlévé.—Observations of Leonids made at Athens, by M. D. Eginitis. On the nights of November 14, 15 and 16 the conditions were favourable for observations, and in all some 147 meteors were seen. They were generally red and brilliant, and appeared to radiate from two distinct points separated by some degrees.—On the deformation of surfaces and of quadrics in particular, by M. L. Raffy.—On the number of roots common to several equations, by M. G. Tzitzeica.—On an application of the prism of Govi to the realisation of an apparatus for verifying rules, by M. A. Lafay.—A method allowing of the evaluation in absolute measure of very low temperatures, by M. Henri Pellat. It has been known for some time from the researches of Lord Kelvin that the rate of change of the electromotive force of a thermocouple with the temperature is equal to the ratio of the coefficient of the Peltier effect to the absolute temperature. A method is sketched out by the author in which this relation is applied to the practical calibration of a thermocouple in absolute temperatures. It is estimated that the method would permit of an accuracy of 0°·5 in the neighbourhood of 150° C. absolute, and of from 1° to 1°·5 at 75° and 20° absolute.—The application of the Lagrangian equations to electrodynamical phenomena, by M. E. Carvallo.—On the disruptive discharge in electrolytes, by M. H. Bagard. Methods are described by which the results obtained by MM. Broca and Turchini in the case of disruptive discharge of electrolytes that are good conductors can be reproduced in a much simpler manner.—On the spark of the Hertz exciter, by M. C. Tissot. A photographic study of the sparks given by a transmitter used in wireless telegraphy shows that the images of successive sparks are not rigorously equidistant, the first being always longer than the others. This appears to be connected with the fact observed by M. Hemsalech, that the spectrum of the first discharge contains only air lines, whilst the rays of the metal appear in the others.—On the induced radio-activity produced by radium salts, by MM. P. Curie and A. Debierne.—The influence of radio-active substances on the luminescence of gases, by M. Alix de Hemptinne. It has been found that if a radio-active substance is brought near a tube containing air at low pressure and submitted to electrical vibrations, it becomes luminous at a higher pressure than is the case if the radio-active substance is not present, the light, which was of a violet-red colour in the latter case, being a greenish-yellow under the action of the radium.—Contribution to the study of the tin-aluminium alloys, by M. Leon Guillet. Two well-defined alloys of tin and aluminium have been isolated in the form of crystals, corresponding to the formulæ $AlSn$ and Al_4Sn.—The action of pyridine bases on the tetra-halogen derivatives of quinones, by M. Henri Imbert.—On *Dorstenia klaïneana*, and on the chemical composition of its root compared with that of *Dorstenia brasiliensis*, by MM. Heckel and F. Schlagdenhauffen.—The composition of the reserve carbohydrates in the albumen of the seeds of some Liliaceæ and in particular of the butcher's broom, by M. Georges Dubat. The hydrolysis of the seeds gives about 70 per cent. of reducing sugars, of which about one-fifth is invert sugar, two-fifths glucose, and two-fifths mannose.—On the constitution of wheat, by M. E. Fleurent.—On the modifications which the hæmoglobin of the blood undergoes under the influence of a reduction in the atmospheric pressure, by M. J. Vallot. From experiments carried out on Mont Blanc it was found that the rarefaction of the air produces immediately in man an increase in the activity of the exchanges, tending to compensate the deficiency of oxygen. Fatigue tends to oppose this increase, and may so far overbalance it as to produce mountain sickness. But this effect disappears after prolonged rest at a high altitude, and the increase in the activity of the exchanges goes on for some time until the body becomes acclimatised. On descending, the return to the normal rate of exchange is prolonged in proportion to the length of sojourn above.—The physical and chemical phenomena of respiration at different altitudes during a balloon ascent, by MM. J. Tissot and Hallion.—New researches on the dissociation of carbonoxyhæmoglobin, by M. N. Gréhant. The destruction of carbonoxyhæmoglobin existing in the blood is much more rapid when pure oxygen is breathed than when air is breathed; in the latter case the amount of carbon monoxide in the blood remains constant for nearly twenty minutes after the breathing is commenced.—Researches on the effect of the stings of *Latrodectus* 13-*guttatus*, by M. L. Bordas. In Corsica and other countries the effect of these stings is considered very dangerous, but it is shown in the present series of experiments that such stings are never mortal in man or the larger animals, although proving rapidly fatal to certain insects, coleoptera and orthoptera.—The influence of diseases of the parents upon the imperfections of the offspring. Tuberculous lesions without microbes, by MM. A. Charrin and Gabriel Delamere.—On two diseases of the leaves of chrysanthemums not previously described, by M. H. Joffrin.—On the existence of a principle, toxic to the pear tree, in the berries, seeds and stems of mistletoe, by M. Émile Laurent.—The phenomena of the capture of superficial water courses by subterranean streams in calcareous districts, by M. E. Fournier.—On the three crystophyllian series of the western Alps, by M. Pierre Termier.—Experimental complement to the history of the striated gravels, by M. Stanislas Meunier.

NEW SOUTH WALES.

Royal Society, October 2.—Mr. H. C. Russell, C.M.G., F.R.S., president, in the chair.—On the relation between leaf venation and the presence of certain chemical constituents in the oils of the Eucalypts, by Mr. R. T. Baker and Mr. Henry G. Smith. In this paper the authors show that there exists a marked agreement between the venation of Eucalypts leaves and the characteristic constituents in their oils. The venation shown by the leaves of the "bloodwoods" *E. corymbosa*, *E. trachyphloia*, &c., is indicative of a predominance of pinene in the oils and an absence of phellandrene. It is this end of the Eucalyptus series that is more closely associated with the Angophoras, because the venation of the leaves is similar and the chemical constituents in agreement.

As the series descends through such species as *E. botryoides*, *E. saligna*, &c., we reach those Eucalypts of which the principal oil constituents are pinene and eucalyptol, the latter constituent increasing in amount until such excellent eucalyptol oils as those of *E. globulus*, *E. Smithii*, *E. longifolia*, &c., are reached. The venation of the leaves of these species is similar, is more open, the individual lateral veins having become more distinct, and with the bending of the marginal vein, commencing to form the looping so characteristic of the phellandrene-peppermint group, the species of which include those of *E. dives*, *E. radiata*, *E. amygdalina*, *E. Sieberiana*, &c. The principal constituent in these oils is phellandrene, and at the extreme end this constituent is present in such abundance as to exclude, almost entirely, the eucalyptol. The pinene which was such a prominent constituent in the oils of the earlier members of the series is only present in the oils of this group in minute quantities. The looping appearance of the venation of the members of the phellandrene-peppermint group has become more open, and the spaces between the principal lateral veins are larger. With the subordination of many of the original lateral veins the spaces provided for the formation of the oil glands is larger, and consequently we find these more numerous in the members of this group; the yield of oil obtainable is therefore much greater, and it is this feature which enables such enormous yields of oil to be obtained from such species as *E. amygdalina*, *E. dives* and *E. radiata*.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 12.

ROYAL SOCIETY, at 4.30.—On the Action of the Spurge (*Euphorbia hiberna*, L.) on Salmonoid Fishes: Dr. H. M. Kyle.—Contributions to the Chemistry of Chlorophyll. No. VIII. Changes undergone by Chlorophyll in passing through the Bodies of Animals: Dr. E. Schunck, F.R.S.—The Result of Chilling Copper-Tin Alloys. Second Communication. C. T. Heycock, F.R.S., and F. H. Neville, F.R.S.—The Effective Temperature of the Sun: W. E. Wilson, F.R.S.

MATHEMATICAL SOCIETY, at 5.30.—Flexure of a Circular Plate: J. H. Michell.—Non-uniform Convergence, and the Integration of Series: Dr. Hobson, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Physical Properties of certain Aluminium Alloys and some Notes on Aluminium Conductors: Prof. E. Wilson (conclusion of discussion).—Some Principles underlying the Profitable Sale of Electricity: Arthur Wright.

CHEMICAL SOCIETY, at 8.—Extraordinary General Meeting.

FRIDAY DECEMBER 13.

PHYSICAL SOCIETY, at 5.—On Circular Filaments and Circular Magnetic Shells equivalent to Circular Coils, and on the Equivalent Radius of a Coil: Prof. Thomas R. Lyle.—Air Pressures used in playing Brass Instruments: Dr. Barton and S. C. Laws.—A New Hygrometric Method: E. B. H. Wade.

ROYAL ASTRONOMICAL SOCIETY, at 5.—The Observed Motion and Duration of the Radiant Point of the Leonids: W. F. Denning.—Observations of Nova Persei: J. E. Gore.—Apparent Paucity of the Leonid Stream: Rev. S. J. Johnson.—Contribution to the History of the Reflex Zenith Tube: S. C. Chandler.—*Probable Papers*: On the Accuracy of Measures on Photographs: Remarks on Recent Papers by M. Lœwy and Mr. H. C. Plummer: A. R. Hinks.—Description of Adams's MSS. on the Perturbations of Uranus: R. A. Sampson.

MALACOLOGICAL SOCIETY, at 8.—On the Anatomy and Relationships of *Voluta musica*, Linn.; with Notes upon other supposed Members of the *Volutidae*: S. Pace.—Descriptions of a New East African *Ennea* and a N.W. Australian *Thersites* (*Rhagada*): H. Fulton.—*Eulota blakeana*, Newc., and *E. luna*, Pils.: G. K. Gude.—Note on the Pairing of *Pyramidula rotundata* with *Vitrea lucida*: Mons. Caziot.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Dysentery in Asylums: Dr. Mott, F.R.S.

SATURDAY, DECEMBER 14.

ESSEX FIELD CLUB (at Essex Museum of Natural History, Stratford), at 6.30.—Contributions to the Pleistocene Geology of the Thames Valley. I. The Grays Thurrock Area, Part II.: A. C. Hinton and A. S. Kennard.—The Water-Mites (Hydrachnidæ) of Epping Forest: C. D. Soar.—Manganiferous Nodules in the Boulder-clay Soils of Essex: Miss Thresh.

MONDAY, DECEMBER 16.

SOCIETY OF ARTS, at 8.—The Chemistry of Confectioners' Materials and Processes: William Jago.

IMPERIAL INSTITUTE, at 8.30.—The Economic Resources of the Straits Settlements and the Malay Peninsula: H. N. Ridley.

TUESDAY, DECEMBER 17.

ZOOLOGICAL SOCIETY, at 8.30.—On the Structure of the Larval *Polypterus*: J. S. Budgett.—On the Spawn and Young of a Polychæte Worm of the Genus *Marphysa*: L. A. Borradaile.—On the Anatomy of Gruiform Birds, with Special Reference to the Correlation of Modifications: Dr. P. Chalmers Mitchell.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Motive Power from Blast-furnace Gases: Bryan Donkin.

ROYAL STATISTICAL SOCIETY, at 5.—The Suspension of the Berlin Produce Exchange, and its Effect on Corn Prices: R. H. Hooker.

WEDNESDAY, DECEMBER 18.

SOCIETY OF ARTS, at 8.—Range Finders: Prof. George Forbes, F.R.S.

GEOLOGICAL SOCIETY, at 8.—Coal- and Petroleum-Deposits in European Turkey: Lieut.-Colonel Thomas English.—(1) On the Geological and Physical Development of Dominica, with Notes on Martinique, St. Lucia, St. Vincent and the Grenadines; (2) On the Geological and Physical Development of Barbados, with Notes on Trinidad: Prof. J. W. Spencer.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Further Observations and Conclusions in relation to Atmospheric Transparency: Hon. F. A. Rollo Russell.—Remarkable Phosphorescent Phenomenon observed in the Persian Gulf, April 4 and 9, 1901: W. S. Hoseason.—On the Mechanical Principle of Atmospheric Circulation: Captain R. A. Edwin, R.N.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Development and Structure of Eyes, illustrated by Micro-slides: F. W. Watson Baker.

THURSDAY, DECEMBER 19.

LINNEAN SOCIETY, at 8.—On the Brain of Recent and Fossil Lemurs: Dr. G. Elliot Smith.—On the Ostracoda collected round the Funafuti: F. Chapman.—Exhibitions: A Gigantic Argulus from Japan and a Specimen dredged at the Cape: Prof. G. B. Howes, F.R.S.—A New Polyzoon from Tanganyika: J. E. S. Moore.—An Example of White's Thrush (*Turdus varius*), shot near Clavering, Essex: Miller Christy.

CHEMICAL SOCIETY, at 8.—(1) Corydaline. Part VII. The Constitution of Corydaline; (2) The Relation of Corydaline to Berberine. The Oxidation of Berberine with Nitric Acid: J. J. Dobbie and A. Lauder.—The Magnetic Rotation of some Polyhydric Alcohols, Hexoses, and Disaccharoses: W. H. Perkin, F.R.S.—Stereoisomeric Halogen Derivatives of α-benzoylcamphor: H. O. Forster and F. M. G. Micklethwait.—Is Argon an Elementary Substance? G. Martin.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.

FRIDAY, DECEMBER 20.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Transmission Dynamometers: A. M. Morgan.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—The Microscopical Examination of the Alloys of Copper and Tin: W. Campbell.

THE FACE OF THE EARTH.

Das Antlitz der Erde. Von Eduard Suess. Mit 23 Textabbildungen, 6 Tafeln und einer Karte der Scheitel Eurasien's. Dritter Band. Erste Hälfte. Pp. iv + 508. (Wien: Tempsky, 1901.) Price 25*s.* net.

La Face de la Terre. Par Eduard Suess. Traduit avec autorisation de l'Auteur et Annoté sous la Direction de Emmanuel de Margérie. Tome II. Pp. 878. (Paris: Colin, 1900.)

SINCE the publication of Lyell's "Principles" no general treatise on geology has aroused more interest or exercised a more important influence on the evolution of geological ideas than "Das Antlitz der Erde," the first two volumes of which were reviewed in NATURE of April 25, 1889. Thirteen years have elapsed since the second volume appeared. It left the plot—if we may be allowed to use that expression—in a somewhat complicated condition, but the interest was maintained and not a little curiosity was aroused as to how the distinguished author would weave the various threads together. The first part of the last volume is now before us, but the mystery is not solved. We must wait with such patience as we can command until the conclusion appears.

As the leading ideas which run through the entire work may not be familiar to all readers of NATURE, a brief account of them will be given before proceeding to the review of the new volume. It must, however, be remembered that the work contains a careful and elaborate statement of facts relating to the structure of almost every part of the world, and is, therefore, of great value as a work of reference, quite apart from the truth or error of the theoretical views of the author.

A study of the structure of the earth's crust proves that it has been affected by two types of movement—the one characterised by a compression of the stratified rocks along certain zones, the other by a separation of the crust into blocks, some of which have sunk down relatively to others. The first type is best illustrated in modern mountain ranges, such as the Alps and Himalayas, the second in districts which have not recently been affected by folding movements.

One and the same area cannot be simultaneously affected by these two types of movement, but a folded zone may, after the folding stresses have ceased to act, be broken up by more or less vertical faults and by the sinking down of certain portions. It is probable that no part of the earth's surface has escaped the action of lateral pressure, but large tracts—as, for example, the north of Russia—have not been affected by it since pre-Cambrian times.

By the sinking of certain areas ocean basins are formed, enlarged or deepened, and terrestrial features like the Great Rift Valley of Central Africa are produced. When the sinking process takes place those parts of the crust which remain stationary, or which do not sink so much as the others, are termed "horsts." According to the author, the continents are of the nature of "horsts"; they have not been formed by elevation, but by the sinking of the intervening tracts.

In support of such a view he refers especially to the fact that no proofs of the presence of a Mesozoic sea are to be found over southern India or the corresponding portion of Africa. On the contrary, the continental deposits of the Gondwana and Karoo series end off abruptly against the ocean. Such facts as these are, he considers, incompatible with the view that continents have been formed by elevation.

But although the existing oceans have been formed by depressions, it must not be supposed that all parts of any one ocean are of the same age, any more than that the continents have been formed by one simple or continuous process. The modern Atlantic, for example, has probably been produced by an enlargement in a northern and southern direction of Neumayr's Centrale Mittelmeer.

The geologist, however, has not only to deal with movements of the earth's crust, but also with changes in the relative level of land and sea. In speaking of such movements Prof. Suess considers that we should adopt a phraseology independent of theory. A rise of sea-level he terms a positive movement and a sinking of the sea-level a negative movement. The Black Sea and the Ægean Sea are both of quite recent date. If no water occupied these areas before the sinking took place, a lowering of the sea-level all the world over to the extent of about four metres must have been produced when they were formed. The crust of the earth breaks in and the sea follows; but whilst the depressions of the lithosphere are limited in extent the lowering of the sea-level is universal.

If we study the succession and distribution of sedimentary deposits we find, over large areas, clear evidence of transgressions or, in other words, of positive movements; these must have been of great extent and duration. Comparative stratigraphy shows that the positive and negative movements are too widely extended to be due to local movements of elevation and depression affecting the solid crust. Thus the Upper Cretaceous transgression, which forms such a striking feature in the geology of southern England, makes itself felt on the Amazon, on the Athabaska and on the Elbe, on the banks of the Nile and in the Tarim Basin, in the valley of the Narbudda and in Borneo, in the island of Sachalin and on the banks of the Sacramento.

The very fact that we are able to employ the same terminology to distinguish the broader sedimentary groups in all parts of the world is a proof that the limits of these groups have been determined by general and not by local causes. England is peculiarly well adapted to furnish the basis for a general classification, because the more important negative movements are here clearly marked out by the intercalation, in the marine series, of continental or fresh-water formations; and the limits established by William Smith and his successors correspond, for the most part, to these movements. At the commencement of a negative phase portions of the oceanic areas become isolated, saline and gypsiferous deposits are formed and the marine fauna becomes impoverished, but its final disappearance only takes place after the negative phase has reached its maximum.

It must not be supposed that the movements are continuous. Just as the actual limit of the water is continually oscillating backwards and forwards during the rise and fall of the tide, so it is with the positive and negative

movements which are recorded in the rocks; the positive movements appear to last much longer than the negative movements which follow them. From the Rhætic to the Callovian in Europe there was an encroachment of the sea upon the land subject only to minor regressions, but the succeeding negative phase which is marked by the Portlandian and Purbeckian was of comparatively short duration.

How are these slow positive movements to be accounted for? The deposition of sediment necessarily tends to produce a continual rise of the sea-level. The formation of the Black Sea and the Ægean Sea, as we have pointed out, would account for a general lowering of the sea-level to the extent of 4 metres; but to produce a corresponding movement in the opposite direction by denudation and deposition would require the transference of an amount of solid rock equivalent to the lowering of the general surface of the land by as much as 10 metres.

The author, however, hesitates to draw the conclusion that the principal positive movements are the result of this cause, and favours the idea that, in some unknown manner, the waters of the ocean have been alternately heaped up at the equator and the poles.

We turn now to the volume which forms the more immediate subject of this review. It deals mainly with those portions of Asia on which so much light has been thrown during the last decade by the indefatigable researches of Russian geologists; the method of treatment is that with which all readers of the first two volumes are familiar. Broad generalisations are suggested in a few words, and then follows a mass of local detail which it is impossible to understand fully without better maps than those which illustrate the work or which are to be found in any ordinary atlas. We look forward with interest to the publication of the French translation, for in the matter of maps and illustrations the French editions of the first two volumes are superior to the original German work. We owe a deep debt of gratitude to M. Margérie and the other distinguished French geologists who have taken so much pains in the translation of this remarkable work and in the selection of additional maps and illustrations.

Different observers have taken different views as to the structure of Asia, but all are agreed as to the existence of a certain uniformity of plan. Prof. Suess calls attention to the predominance of bow-like forms. Such forms are seen on the shores of the Pacific and in the festoon-like arrangement of the adjacent islands, on the Ganges, the Indus and in Iran. The bows may be strongly or weakly bent, crowded together or separated from each other, but they are always arranged in such a way as to suggest a relation to some central nucleus. This nucleus the author finds in the neighbourhood of Irkutsk and Lake Baikal. It is a region of Archæan gneisses and schists which has been broken up into "horsts" and "sinkings." The great amphitheatre of Irkutsk which is drained by the Angara forms a notch in "the old nucleus" (der alte Scheitel). It has been formed by sinking and is bordered by powerful faults.

As the nucleus is approached, the forms of the mountains change. In the neighbourhood of the sea volcanoes occur; further inwards the snow-clad peaks of the giant mountains form the dominant features; to these succeed the rock-walls of the Gobi, which rise above the lower ground formed of horizontally stratified deposits. From the Altai to the region south of Lake Baikal and onward to the Upper Amur, the features are characteristic of an old mountain land which has been more or less completely worn down by denudation. The mountains here have rounded summits, and rest on broad bases. The river systems are fully developed, and when rapids occur they can be traced to comparatively recent changes, such as the outpouring of basalt. These are the characteristic features of the old nucleus. To the north of this nucleus the elevations are tabular and are often formed of flat-lying Palæozoic strata capped by later basalts. In the tundra region of the extreme north, marine horizontal strata give evidence of the Mesozoic transgression.

So far we have been referring only to the introduction. The second section deals with Siberia, which is divided into two well-marked areas, the west Siberian plain and the east Siberian tableland. The only eminences which rise above the alluvial flats in the western plain, between the Yenesei and the Obi, are relics of a once extensive sheet of soft Tertiary sandstone. The Middle Jurassic transgression, which is traceable from the Arctic regions over the Petchora to Cracow, extends from Russia through the low grounds of Turan to Baluchistan and round the shores of the Indian Ocean, but has not as yet been recognised in western Siberia. The only traces of the widespread Upper Cretaceous transgression occur in western Siberia at Ajat, in the south-west corner. Marine deposits with characteristic European fossils here lie on folded Palæozoic strata.

The Tertiary seas (Upper Eocene and Lower Oligocene) gained access to Siberia through the Straits of Turgai (south of the Urals), and reached as far as Semipalatinsk and Sosswa. About the middle or end of the Oligocene period, all connection with the European seas was cut off and the flora of the amber forests spread over the regions vacated by the sea. This great negative movement led to the isolation of oceanic areas both in Europe and Asia, and to the formation of extensive salt-deposits.

The east Siberian tableland is bounded on the south by the old nucleus, on the north-east by the bow of the Werchogan Mountains, on the north-west by the mountains of the Taimyr Peninsula and on the north by the frozen sea. The Lena belongs to the tableland, and flows in a valley which is often 300 metres deep. Four elements take part in the structure of this plateau region. The first is the Palæozoic floor, which probably underlies the whole. The lowest beds belong to the *Olenellus* zone. They are horizontal except on the borders of the amphitheatre of Irkutsk. This amphitheatre has already been referred to as a sunken portion of the old nucleus which is bordered by powerful faults. Folding and even overfolding are associated with these faults, and the direction of overfolding, as so frequently happens under similar circumstances, is directed towards the centre of the sunken tract.

The second element consists of plant-bearing beds, which often contain workable coal. *Asplenium whitbyense* is common, and the deposits were referred by Heer to the Middle Jura. The rocks are sandstone and conglomerate. Plant-bearing beds of the same general type

are widely distributed in Central Asia, and it is practically certain that they are not all of the same age; thus Zeiller has recognised affinities with the Gondwana flora and has referred certain deposits occurring in the Altai Mountains to the Permian period. From a consideration of these plant-bearing deposits the author is led to an interesting generalisation. They indicate a Mesozoic continent on the north comparable with Gondwanaland on the south. Between the two lay Neumayr's Centrale Mittelmeer (the author's Tethys), the marine deposits of which are now traceable in a broad zone stretching from Timor and Sumatra through Tonkin, Yunnan, the Himalaya, Pamir and Hindu Kush to Asia Minor and Europe. Modern Asia owes its origin, therefore, in great measure, to the disappearance of Tethys, the rucking up of its sediments into mighty mountain ranges and the consequent union of Angaraland on the north with the Indian fragment of Gondwanaland on the south.

The third element which enters into the structure of the east Siberian tableland consists of Mesozoic marine deposits, indicating encroachments of the sea from the north at various periods. They have not as yet been traced further south than 62° N. lat., but as the plant-bearing beds of the Angara series have been found in higher latitudes it is certain that the northern boundary of Angaraland must have oscillated backwards and forwards during the Mesozoic period. The marine deposits include representatives of the Middle Lias, Oxfordian, the Volga series and the Neocomian.

The fourth element consists of widespread sheets of basaltic lava. One of these sheets extends from latitude 60° 15′ on the Lower Tunguska to the mouth of the Yenesei. It covers about 6° of latitude and 9° of longitude. These basalts do not stand related to definite volcanic cones. They are of the true plateau type and are thus brought into connection with the basalts of Franz Josef Land and of the Brito-Icelandic province.

On the Lower Tunguska they are associated with deposits of the Angara series, and, although true lavas occur, it is not improbable that the sediments were invaded and sometimes broken up by vast intrusions of a sill-like character, which separated and floated off large masses.

The third section of the work deals with the old nucleus (der alte Scheitel). This extends from the Yenesei above Krasnoyarsk eastwards to the Great Chingan range and as far south as the Gobi Altai. East of Lake Baikal the dominant strike is south-west or west-south-west, west of Lake Baikal it is south-east or east-south-east. These two dominant strikes were produced by pre-Cambrian earth-stresses, but they have determined the directions of the later folding and faulting on the borders of the amphitheatre of Irkutsk and in other regions.

In addition to granites, gneisses and schists, the only rocks entering into the composition of the area in question are fresh-water Tertiary formations and basalts—the latter are allied to those occurring in the tableland of east Siberia. The period of eruptions must have been of great duration, for basalt is found, not only capping the ancient hills of gneiss and schist in horizontal sheets, but occurs also in the beds of existing valleys. The district has been broken up into "horsts" and "sinkings," which are described in great detail from the writings of Russian geologists. Many of the "sinkings" are shown to be of the rift-valley type (Gräben).

The fourth section treats of the Great Chingan range, the plain of the Upper Amur, the Aldan mountains, the Lesser Chingan, Manchuria, Sichoto-Alin, Hokkaido, Sachalin and the Japanese islands. Over the whole of this vast area the author recognises a common type of structure. We will give his views as nearly as possible in his own words.

"In the fruitful plain of the Amur, through the dark primeval forests of the Turkana mountains and the Lesser Chingan as far as the deserts of Sachalin and the great oceanic depths off the Japanese coast, a common arrangement of the leading lines (Leitlinien) finds expression in the convergence of all the curved mountain ranges towards the north of the Sea of Okhotsk. . . . Could we remove the waters of the ocean we should then see the curved rows of islands standing out as mighty mountain ranges. Curve follows curve (Bogen reiht sich an Bogen), and the wonderful agency by which all these curved chains have been produced appears to have proceeded outwards from the central nucleus and to have extended its operations beyond the limits of the modern coast-line."

As the Pacific Ocean is approached, marine deposits of Mesozoic age are met with and traces of the Middle Cretaceous transgression are found in the island of Sachalin. But the plant-bearing beds of the Angara series occur in the plain of the Amur and in Manchuria, thus indicating an extension of Angaraland which has been dropped down in successive steps towards the east by faults and flexures. In spite of this, however, the land area must have increased where the marine Mesozoic strata occur. This increase may have been caused in part by folding, but is probably due, in the main, to a draining off of the sea-waters to fill oceanic depressions formed elsewhere.

Angaraland, which in some parts of Asia goes back to the Carboniferous and in others at least to the Rhætic periods, furnishes an illustration of the permanence of continental areas, though not in the sense in which that expression is usually employed. Since life first appeared on the planet, the phylogenetic thread has never been broken, although evolution has not been continuous and uniform. For the dwellers on the land and in fresh-water the continuity of this thread requires the permanence of continental areas for long periods. Angaraland must, therefore, have been of great importance from a biological point of view. Throughout a large portion of geological time it must have been, not only a retreat for terrestrial and fresh-water forms of life, but also a land capable of sending out colonists as occasions arose.

Enough has now been said to give an idea of the nature of the book and of the method of treatment adopted by the author. The contents of the remaining sections will only be indicated. The fifth and sixth deal with the Altai and the more or less related chains which the author groups under the name of the Altaides; the seventh with the Yarkand-arc and with Iran and Turan; the eighth with the principal ranges of Asia Minor; the ninth and last treats of northern Europe.

Geologists may differ on many points discussed by the author, but no one can complain of the way in which he has presented his views. He is never dogmatic. His

method is to marshal the facts and suggest the conclusions to which they point. One of the most delightful characteristics of the book is the sympathetic interest which the author shows, on almost every page, in the labours of other workers. His sympathies are as all-embracing as the views which he has formed as to the origin of terrestrial features.

The French translations of the first two volumes have already been referred to. The extensive knowledge and great literary skill of M. E. de Margérie, under whose direction the translation has been carried out, are a sufficient guarantee of the excellence of the work. It has evidently been a labour of love with the translators, who have treated their author with that respect which should always be shown in such cases. In two respects the translations are better than the original work. The number of maps and illustrations has been greatly increased (128 as against 43 for the second volume), and the notes, which are voluminous and often very important, are given at the foot of the page to which they refer instead of at the end of each section. Moreover, the notes and references have been brought up to date, but all additions are indicated by the use of square brackets. J. J. H. T.

THE CHEMISTRY OF DYEING.

A Dictionary of Dyes, Mordants and other Compounds used in Dyeing and Calico Printing. By Christopher Rawson, F.I.C., F.C.S., Walter M. Gardner, F.C.S., and W. F. Laycock, Ph.D., F.C.S. Pp. 372. (London: Charles Griffin and Co., Ltd., 1901.) Price 16*s.* net.

THE technology of dyestuffs and dyeing materials has acquired in recent years such a degree of complexity that a dictionary of the subject has become almost a necessity. This want is now supplied by the handy volume before us. Although essentially a dictionary and not to be regarded in the light of a text-book, it nevertheless contains many excellent articles on the chemistry and technology of textile fibres and colouring matters, and should be a most valuable work of reference for all engaged in the arts of dyeing, bleaching, calico printing, paper staining, &c. The book is issued as a companion volume to the well-known "Manual of Dyeing," by Knecht, Rawson and Loewenthal, to which in some respects it serves as a supplement. The methods for the commercial analysis of the various chemicals, mordants and dyeing materials are treated with considerable detail. With regard to colouring-matters a careful system of classification is employed, each group being given a special article, *e.g.*, acid colours, basic colours, direct cotton colours, mordant dyes, &c., and under each of these headings we find a fairly complete list of all the colouring-matters of the particular group at present in use. For further information with regard to individual dyestuffs, each name must be separately consulted. Excellent general articles are also to be found upon indigo, tannin matters, action of light upon dyes, and upon the analysis, valuation and detection of coal-tar colours.

On the other hand, besides a few superfluous articles having little or no bearing on the subject of dyeing (*e.g.*, the headings Acetaldehyde, Acetanilide, Antifebrine, &c.), there are some serious omissions. Thus no method is given for examining the quality of commercial betanaphthol, a matter of much greater importance to the dyer or printer than the isomerism of the sulphonic acids of dioxynaphthalene or of alphanaphthylamine, the reference to which might well be omitted. Again, there is no article upon paranitraniline, but only a cross reference under "Paranitraniline red" to "Azo colours on cotton," where no description is to be found of the properties or methods to be employed in examining for purity this most important product. The same remark applies to dianisidine, only "Dianisidine blue" being referred to under "Azo colours on cotton." The heading of the last-mentioned article should surely have been "Insoluble azo colours on cotton" or "Azo colours produced on the cotton fibre," since all the substantive benzidine colours when applied to cotton might equally be styled "Azo colours on cotton." We also fail to find any reference to sodium sulphide, bronze colours, discharges, persulphates or titanium mordants.

Under the individual colouring-matters there might have been given in some cases a rather fuller account of the special tinctorial properties and degree of fastness to reagents (soap, alkalis, acids, &c.) To provide for these additions considerable space might have been saved by the omission of the names of obsolete colouring-matters and of obsolete names of colouring-matters still used (for instance, aldehyde green, azuline, canelle, heliochrysine, and many others).

A few errors are noticeable in the text, as, for instance, in the article "Janus colours," which latter are stated to be sulphonated basic dyes, whereas in fact they contain no sulphonic group, but are azo-compounds, which owe their solubility and peculiar dyeing properties to the presence of strongly basic ammonium or azonium groups. Again, thioflavine T is given as a derivative of primuline, whereas it is the methylated ammonium compound of dehydrothiotoluidine. The list of manufacturers of colouring-matters given on p. 94 and also opposite to p. 1 is scarcely up-to-date, one of the firms mentioned having ceased to exist, whilst two others have been reconstituted under new names. In spite of the above defects, which can readily be rectified in subsequent editions, the work may be confidently recommended to all engaged in the textile and tinctorial industries as an invaluable lexicon of the subject.

ANIMAL LIFE OF THE CONGO FOREST.

The World of the Great Forest; How Animals, Birds, Reptiles, Insects Talk, Think, Work and Live. By Paul du Chaillu. Pp. xv + 323. Illustrated. (London: Murray, 1901.) Price 7*s.* 6*d.* net.

IN the outlandish and almost unpronouncable native names of animals which form the chapter-headings and recur with wearisome iteration in the text, this volume reminds us of Longfellow's "Hiawatha," although, in our opinion, without affording anything comparable to the pleasure which may be experienced in reading the latter. The author appears to have taken as his model that delightful book of Mr. Seton-Thompson's, "Wild Animals I Have Known"; but if so he has, we think, succeeded in producing only a very poor and feeble

imitation. We have submitted Mr. Du Chaillu's volume to several friends of diverse ages and sexes in the hope of obtaining an opinion as to the class of readers for whose benefit it is specially intended, but in no instance have we succeeded in obtaining a definite answer on this point. One thing is perfectly certain, namely, that no scientific naturalist will gain any information worth having from a perusal of its pages. A lady suggested hat it was like a book for very young children, without being sufficiently amusing.

The author, who firmly believes that animals have a definite language by means of which they communicate their ideas, not only to their own fellows, but to the members of other species as well, had a grand subject before him in describing the life of the denizens of the great Congo forest. But, in our opinion, the conversation he has put into the mouths of the animals is the merest drivel. And when animals, such as leopards antelopes and elephants, have familiar English names, we quite fail to see the advantage of alluding to them, by their negro titles, apparently for the sake of translating them. When an animal like *Tragelaphus euryceros* has no good English name, it is right and proper that its native title—in this case "bongo"—should be employed; but the substitution of "kambi" for antelope is merely confusing. Neither is the work altogether free from absolute errors, while in several instances statements that have been controverted reappear as though they were undoubted facts. As an example of the former class we may refer to the statement on p. 42 that "large flocks of toucans (a bird with a huge bill)" are among the denizens of the Congo forest! As an instance of the second kind, it may be mentioned that (pp. 154–155) the author revives the old story of the gorilla advancing to the attack in the upright posture, beating his breast with his fists. We thought this story had been disposed of by Winwood Reade, who denies that du Chaillu ever saw a living gorilla in the wild state; and, so far as we are aware, no subsequent traveller, with better information at command, has ever said a word in its support.

Again, several of the incidents related appear absolutely incredible. For instance, on p. 95 we have a wonderful picture of a gorilla struggling to free himself from a porcupine on which he had incautiously trodden in his descent from a tree. Bearing in mind the well-known power in wild animals of detecting the presence of other creatures, such an event requires the most convincing testimony to render it credible, and yet it is related without special comment. In another chapter (p. 160) we are told how a python coiled around a tree-trunk "made a tremendous spring" and in an instant was coiled tightly round the body of an unfortunate antelope, which it squeezed to death. How a python could make the spring in question and at the same time disengage itself from the tree around which it was coiled we are not told. As a minor matter, a small inaccuracy in connection with this anecdote may be mentioned. In the accompanying illustration the antelope, which is evidently one of those species of which the females are unarmed, is represented with horns, and yet in the text it is alluded to as a female.

Although it is certainly incorrect to call a land-tortoise a turtle (p. 101), this confusion in terms may perhaps be excused on account of the author's nationality. A similar excuse cannot, however, possibly be made for the statement on p. 266 that "a pack of ugly-looking striped hyænas" advanced into the moonlight. In the first place, striped hyænas are quite unknown in West Africa; and, in the second, the author is refuted by his own draughtsman, who, in the plate on the opposite page, has figured an unmistakable group of *spotted* hyænas. Moreover, if we mistake not, the illustration in question is based, without acknowledgment, on a picture which has already appeared elsewhere.

Neither can we congratulate the author on his views with regard to the *raison d'être* of the coloration of certain animals. It has, for instance, been almost conclusively proved by Mr. Pocock in this Journal (vol. lxii. p. 584) that the striking type of coloration prevalent among the harnessed antelopes is strictly protective. And yet, when referring to the bongo (a member of the group), the author (p. 223) writes as follows:—

"'My beauty is my curse, dear kambis and ncheris,' replied the bongo; 'my yellow colour and my white stripes are my bane, for my enemies, which are also yours, can spy me further and quicker than they do you.'"

Quite apart from the misapprehension of the object of the bongo's colouring, it may strike the reader of this marvellous book that animals thus endowed with the "knowledge of good and evil," as indicated by their conversation, might have been trusted to have devised some artificial mode of concealing themselves from their enemies! R. L.

OUR BOOK SHELF.

Roads; their Construction and Maintenance. By A. Greenwell, A.M.I.C.E., and J. V. Elsden, F.G.S. Pp. vii + 280. (London: Whittaker and Co., 1901.) Price 5*s*.

THIS is a very practical and useful treatise on roads and their maintenance and may be read with great advantage by any intelligent road surveyor. After the dissolution of the turnpike trusts and the handing over of the roads to the charge of the ordinary highway surveyors the main roads of this country became much neglected. The power acquired by County Councils over the main roads, and of District Councils over other highways, has to a certain extent revolutionised the system of road management and a marked improvement has taken place. The use of the cycle and the motor-car, however, demands a much higher standard of efficiency than was ever before required. There is no doubt that the motor-car, as a means of locomotion and transport, has come to stay and will in future fulfil in many cases functions for which now it is deemed necessary to provide light railways and suburban tramways. For these machines to be used with comfort a clear and even road surface, free from mud and loose stones at all times of the year, is indispensable. The best steam-rolled macadamised roads do not fulfil these conditions. In this respect what are termed tar macadam roads, which have been adopted in a great many suburban districts, not only afford a good surface for traction but, being impervious to wet and not acted upon by frost, are clean and more economical than macadamised roads; they are easily repaired and there is an entire absence of loose stones, equally dangerous for horses and deleterious to rubber tyres. The authors speak favourably of this class of road and describe the system as growing in favour, but the cost as given in

the book is higher than that at which they can be laid in the neighbourhood of provincial towns.

Nearly half the book is devoted to a description of the materials used in the maintenance of roads and to their petrology, a subject which should be carefully studied by road surveyors. The authors very clearly show that it is more economical to procure suitable material from a distance than to employ local stones because the first cost is less. There is a very considerable difference in the wearing qualities of different kinds of stone, the reasons for which are clearly shown in the book.

The chapter on the construction of roads gives information which is now little required in this country, but would be of service to a surveyor in the colonies; those on maintenance and cost contain a great many useful and practical hints. The observations under the last head are well worth the consideration of all authorities having charge of the roads of this country. The authors emphasise what has often been pointed out—that good roads can only be obtained by their being placed under skilled management and by maintaining a high standard of efficiency; that roads maintained in good condition cost less to keep up than those which are allowed to be rutty, uneven and covered with loose stones and mud; and that while unnecessary expenditure is to be avoided, the community ought to understand that money well spent in skilled labour and good material is often saved over and over again in time and convenience.

Morphology of Spermatophytes. By John M. Coulter, Ph.D., and Charles J. Chamberlain, Ph.D. Pp. x+188. (New York: D. Appleton and Co., 1901.) Price 1·75 dollars.

FOR a long time past a comprehensive account of the gymnosperms has been greatly needed, for within recent years many important memoirs have appeared which have thrown much light on the structure and relationships of this interesting family of plants. It is, then, with an anticipatory feeling of pleasure that one opens the first instalment of Messrs. Coulter and Chamberlain's book on the morphology of the spermatophytes, seeing that it is entirely devoted to the gymnosperms. And it may at once be said that the authors have done their work well. The book is more than a critical exposition of our present knowledge, for it embodies also the results of a considerable amount of original research on the plants in question. The illustrations are many and good, and include a large proportion of new figures.

The main groups into which the authors divide the family are dealt with in separate chapters, and *Ginkgo* is treated as the representative of a division coordinate with that of the Cycadales or of the Coniferales. The chief fossil types are also considered, and a somewhat detailed and illustrated description is given, based on a study of Dr. Wieland's preparations, of the structure of the strobilus of *Cycadoidea*.

A due proportion is maintained between the space allotted to the account of internal microscopic structure and of general morphology respectively, although naturally the former, which includes the cytological details, comes in for the greater share. Nevertheless, by no means the least interesting chapters in the book are those dealing with the comparative morphology and phylogeny of the gymnosperms as a whole. The authors would regard them as having a monophyletic origin, traceable to a Filicinean ancestry through the Cycadofilices. They base their opinion mainly on the undoubted descent of the cycads from these forms, and on the difficulty of dissociating the other gymnosperms from the cycads. They do not, however, regard the connection between the different groups as a very close one, and suggest that the Bennettitean stock may have served as the starting-point for the cycads, whilst they would refer Ginkgoales and Coniferales to a Cordaitean ancestry.

They judiciously refrain from dealing very specifically with the Gnetales. The three constituent genera, Gnetum, Tumboa (a name which one regrets to see displacing Welwitschia) and Ephedra differ so widely, both from each other as well as from the rest of the main groups, that they can only be regarded as isolated remnants of some ancient line, the affinities of which it is as yet impossible to do more than guess at.

A short sketch of the geographical distribution of the gymnosperms brings the volume to a close. The authors are to be congratulated on the ability they have displayed in producing a work which is valuable, not only as a text-book, but as a real contribution to science.

Guide Pratique pour les Calculs de Résistance des chaudières a vapeur et l'Essai des matériaux employés. Par G. Huin et E. Maire, avec la collaboration de H. Walther Meunier. "Actualités Scientifiques." Pp. vi+67. (Paris: Gauthier-Villars, 1901.) Price fr. 2.75.

THIS book, consisting of a collection of data and tables relating to boiler construction, is a translation of those adopted by l'Union Internationale des Associations de surveillance d'Appareils a Vapeur, which are in common use in Germany.

Part i. is devoted to formulæ, supplemented by extensive tables, for the determination of the dimensions of the principal parts of boilers.

Part ii. gives the rules relating to the selection of the material and specifies the tests to be used in any case.

The whole book covers about the same ground as the Board of Trade or Lloyd's rules for boilers, considered in greater detail and the calculations assisted by tables. The latter include, thickness of flue plates, for various lengths, diameters and pressures, thickness of shell for iron and steel, with various joints, dimensions and pressures, and the thickness of flat plates under various systems of staying.

The formulæ given are in nearly every case of the same form as those used here, but generally speaking the constants are such as to give slightly smaller dimensions.

This is due to the use of an average factor of safety of 4·5 compared with 5 required by the Board of Trade.

For the thickness of flue the formula given is Bach's

$$t = \frac{p.d}{k}\left(1 + \sqrt{1 + \frac{p}{k'}\,\frac{l}{l+d}}\right) + k'',$$

which should be applicable for a much wider range than our simple

$$t = \sqrt{\frac{p.l.d.}{k}}.$$

There is very little that is not to be found in an ordinary engineer's pocket book. F. H. H.

Ein Wort über den Sitz der vulkanischen Kräfte in der Gegenwart. (*Mittheilung aus dem Museum für Völkerkunde zu Leipzig.*) Von Alphons Stübel. Pp. 15; 9 figures in text, 1 coloured plate. (Leipzig: Max Weg, 1901.)

AS such a difficult subject cannot be discussed in a short notice, it must suffice to give the author's conclusions. He regards the globe as originally a liquid mass, which has become incrusted through loss of heat. This crust at first would be thin and incapable of offering an effective resistance to the struggles of the liquid interior. It would be ruptured at countless points, great floods of lava would be outpoured, without, however, the building up of important volcanic hills. At this epoch the earth may have even been surrounded by a photosphere. In the second stage the crust layer thickens to about 10 kilometres—the phenomena are similar in kind, but correspondingly reduced in extent. In the third stage the crust layer is about 25 kilometres, and the places of

discharge from the liquid interior are fewer. Eruptions come from local reservoirs in the generally solid crust, which, however, may have a communication from beneath with the inner mass. In the fourth stage, when the crust layer approaches 50 kilometres, there is a further decline in number, though an increase in violence, of discharges from the liquid interior, but the activity of the reservoirs is maintained, and henceforth these are the main sources of vulcanicity. That is the age of catastrophic eruption, and the photosphere is disappearing. The next stage continues the cutting off of direct communication with the interior, separation takes place in the masses of magma, and local eruptions are still very violent. This phase may correspond with that stereotyped in the moon. The sixth stage begins, the seventh continues, the deposit of sediments, during which metamorphism is active in the lower beds, thus forming an outer skin to the crust layer. Eruptions continue to affect a plateau type in the earlier of these; the volume of the reservoirs is gradually being reduced, as well as the communications with the more distant interior of the earth. The eighth, in which the liquid reservoirs are few and small, and communication from within any part of the thickened crust layer to the interior very rarely exists, is the present period.

Photographic Cameras and Accessories. Edited by Paul N. Hasluck. Pp. 160. (London: Cassell and Co., Ltd., 1901.)

IT is not often that one meets with amateur photographers who possess cameras made with their own hands, because at the present day instruments can be obtained at such prices that the pocket of even the most modest purchaser can be suited. This is, however, no reason why a camera should not be home-made; and, in fact, besides affording the worker a very pleasant occupation, especially anyone who is interested in carpentry, it redounds to his credit if he turns out a good-looking and serviceable camera and produces first-class pictures with it.

The contents of this little book will afford a very ready and serviceable guide to anyone who wishes to try his hand in this direction, and supply the reader with concise information on the details of the subject of which it treats. As we are told in the preface, the matter consists essentially of a digest of material contributed by a professional photographer to a weekly journal, so that the instructions should be, and are, thoroughly practical. The text is accompanied by a great many working drawings, 241 in number, and deals, not only with the construction of the bodies of cameras, but with dark slides, shutters and stands.

Trattato elementare di Fisica. Da Oreste Murani. Vol. iii. Optics and Electricity. Second edition. Pp. xxi+675. (Milan: Ulrico Hoepli, 1901.)

THIS is a descriptive treatise in which the experimental phenomena in optics and electricity are described and the apparatus used for exhibiting or applying them are illustrated by no less than 593 woodcuts. It is essentially non-mathematical in its treatment, the few formulæ included in the text in connection with such laws as the law of refraction of light and Ohm's law involving no calculus and merely the notation of trigonometry. In regard to modern electrical discoveries and notions, Prof. Murani has brought his treatise very much up-to-date, and the experiments of Righi, Lenard, Hittorf and Hertz on electric discharges, the Röntgen and Becquerel rays, Kerr's, Hall's and Zeeman's phenomena, Tesla's experiments, wireless telegraphy, the coherer and the Wehnelt interrupter, afford instances of the many recent innovations which are described at some length. In the concluding sections the author expresses doubts as to the efficacy of lightning conductors of the old style when the effects of electromagnetic induction are taken into account. The book should be useful both as a class-book in technical colleges, for which purpose it is especially written, and as a work of reference for general readers who wish to acquire some notion of modern electricity and optics without entering into abstruse theories or technical minutiæ.

G. H. B.

A First Course of Practical Science. By J. H. Leonard, B.Sc. Pp. xii + 138. (London: John Murray, 1901.)

EXCELLENT courses of practical work in the rudiments of mensuration and physics are now available in several text-books, but there is still room for volumes like the present one. The exercises described are suitable for quite young beginners, and they will serve the double purpose of applying the pupils' knowledge of arithmetic and developing a scientific frame of mind. Simple measurements of length, area and volume, and calculations (particularly with decimals) referring to them, form the subjects of the opening chapters. Following these are laboratory exercises on weight and centre of gravity, relative weight, atmospheric pressure, thermal expansion, thermometers, latent heat, filtration, solution and distillation.

The experiments are described concisely and are well arranged, so that a pupil of average capacity could perform them without much assistance, and at the same time would acquire clear ideas on fundamental principles. We do not like such expressions as "Have all liquids got a latent heat? Have all gases got a latent heat?" but that is a detail. As a whole the book is satisfactory, and, with others of the same kind, will assist the movement in favour of introducing scientific measurements in early stages of instruction in schools. Dr. Gladstone contributes a short preface.

Coltivazione delle Miniere. By S. Bertolio. Pp. vii+284, with 96 figures. (Milan: Hoepli, 1902 [*sic*]. Price L. 2·50.)

THIS is one of the numerous manuals published by Hoepli of Milan; it contains a useful little epitome of the art of mining. It is not fair to expect too much from a book costing only 2*s*., and consequently one must not carp too loudly at the absence of detailed descriptions and figures of certain important mining appliances. Steam shovels and dredges, which play so weighty a part nowadays, are merely mentioned by name, and hydraulic mining is dismissed in a couple of lines. This defect should be remedied in a second edition, for it is well even in a small manual to impress upon the student the great importance of all mechanical methods of excavation.

On the other hand, the author deserves credit for his picture of the well-marked projecting outcrops of three parallel lodes at Montevecchio in Sardinia; the student has not always the opportunity of seeing such a fine example in the field. Mistakes in foreign words are too frequent, and when the simple name of the inventor of the safety-lamp is spelt "Dawy," the Englishman feels aggrieved; however, all nations are treated alike, for the author is not absolutely faultless in his own tongue.

The Ballads and Shorter Poems of Frederick V. Schiller. Translated into English Verse by Gilbert Clark, M.A. Pp. xv+408. (London: Williams and Norgate.)

SCHILLER'S philosophical writings have admirers in the world of science, and this translation will contribute to the wider appreciation of his poems among people unable to read them in the original. The series of poetical parables and riddles referring to natural phenomena, and the verses on astronomy, astronomers, nature knowledge and transcendental philosophy are of interest to scientific minds.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Humus as a Preservative against Frost.

I HAVE just read a French translation, by my old friend Prof. Henry of the Nancy Forest School, of Wollny's classic work on the decomposition of organic matter. In it I find the statement that spring and autumn frosts are dangerous on peaty soils only when the surface of the latter is dry. Wollny gives no illustrations of this law, but I recently observed one in my garden at Coopers Hill.

Last September I dug up several rose beds on my lawn and sowed them with grass seed, which has produced a fine crop of young grass. This I carefully watered, and the soil in the beds was well trenched and covered with decomposed leaf mould before the seed was sown. The rest of the lawn has not been trenched, probably for thirty years, and the soil under the grass in it, a stiffish loam, is now singularly dry for the time of the year.

On the morning of December 6 there was a slight frost, 31° F. being registered six inches above the grass. At 8 a.m. the lawn was white with rime, except on the new grass, which remained green.

This must be due to the fact that the moist, well-trenched humus soil under the new grass was able to conduct heat from below and thus kept the air in contact with it above the freezing-point, while the dry, compact loam under the old turf could not supply sufficient heat to the old grass to preserve it from freezing. Dry humus, according to Wollny, has a low specific heat and is a bad conductor, while wet humus has a high specific heat and is a good conductor of heat. On another occasion, when snow fell, it melted much sooner on the new grass than on the rest of the garden.

As a further illustration of Wollny's law I may cite the fact that water is let on to cranberry swamps in Carolina when frost is feared during the blossoming period, and also that in north-west India, on clear evenings when frost is feared, vegetable gardens and sugar-cane plantations are irrigated in order to obviate danger from frost.

It is also well known in Germany that if a sphagnum peat bog is to be reproduced, a thin layer of peat must be left at the base of the bog after the upper peat has been removed, and this layer kept carefully under water, as otherwise the drying up and consequent freezing of the peat will kill the moss.

Slight frosts are very prejudicial to vegetation in sub-tropical forests, and, when frost is imminent, the precaution of trenching the soil, removing weeds and irrigating cultivations is extremely important for young sugar-cane and other crops.

Coopers Hill, December 8. W. R. FISHER.

A possible new Petroleum Field near Naples.

WHEN sailing from Posilipo to Sorrento on August 31 last, at about four or five miles from the nearest land of the Sorrentine Peninsula we encountered a most unmistakable smell of petroleum, just as if a leaking petroleum tank steamer had crossed our bows a few moments previously. Two tracks of the smell were distinctly noticeable, the one at lat. 40° 41′ 30″, long. 14° 19′, and the other at lat. 40° 42′, long. 14° 18′ 30″. A moderate *furano* or southerly wind was blowing at the time, so that in all probability the source of the petroleum was somewhat to the south of the position given.

The only other record of a petroleum source in the immediate vicinity of Naples is that of the Balneum Olii Petrolei, or *bagno del petroleo*, which formerly existed near the Stufe di Nerone, between Pozzuoli and Baia. This petroleum bath has now quite dried up, but formerly was much praised by mediæval writers for its curative powers in cases of leprosy and cholera, and also because its waters caused the limbs of bathers to rejoice in new found vigour. The last mention of this petroleum bath was by Bartolo in 1679. In the southern Italian provinces petroleum has been found in considerable quantity at San Giovanni Incarico and at Pico in the valley of the Liri in the district of Gaeta. Indeed, in 1878, 600 tons, or almost all the Italian petroleum, came from this source alone. In the last two decades the annual output has much diminished and has become insignificant as compared with the increased production of the wells in northern Italy. Petroleum has also been stated to occur at Tramutola, on the Gulf of Taranto, and asphalt is recorded from the east side of the Abruzzi, about twenty miles from Pescara on the Adriatic (Redwood).

The depth of the water (80 fathoms) at that part of the Bay of Naples where the smell was noticed is too great for the collection of the petroleum to be commercially practicable. But the long-continued escape of petroleum in the immediate vicinity of the Apennine Limestones of the Sorrentine Peninsula is an indication that deep borings might be successful and might one day yield as profitable a supply of petroleum as the borings in northern Italy. The petroleum fields of the north of Italy near Bologna and Piacenza extend along anticlinals of the Tertiary Limestone, and therefore are geologically similar in many respects to the country in or near which the newly discovered petroleum spring occurs. R. T. GÜNTHER.

Magdalen College, Oxford, December 13.

Automatic Actions.

As Mr. Dixon points out (p. 102), a mental process frequently repeated becomes automatic.

The impulse passes readily along a path in the brain-cells previously frequently traversed by similar impulses, much as a man who revisits the haunts of his youth may, while in a brown study—that is, while abstracting his mind from conscious direction—find his way unerringly through cross-paths, whereas if he had tried to think out his route he would probably have gone astray.

Mr. Dixon's remarks on the different modes of rising of the horse and cow suggest an explanation. I have hitherto regarded the explanation as due to anatomical differences, but the anatomy of animals has been modified by habit and habit by the necessities of environment.

The horse, which couches on the plain in long grass, rises head first. This method gives him an early view over the surrounding grass and keeps his hind legs (his chief propellers) well under him.

The cow, whose natural lair is under low-hanging boughs, rises tail first. This method allows her till the last moment to keep her eyes upon and her horns presented to an approaching foe. W. BENTHALL.

December 7.

VARIATION IN FOWLS.

THE recurrence of the large shows of the different varieties of domestic poultry which occurs at this season of the year gives an admirable opportunity to those interested in the subject of studying the characters of the different breeds, and the almost innumerable varieties produced by crossing them. The study of variation has been a favourite pursuit of mine for more than half a century. When Darwin was preparing his works on the "Origin of Species" and on the "Variation of Animals," he was surprised to find, when I was introduced to him by Yarrell at a poultry show, that I had made a large collection of crania of the different varieties. Of these specimens he availed himself largely in his work on "Variation," in which I had the great pleasure of assisting him. I can, therefore, speak with considerable precision of the great change which has taken place in the breeds of poultry during the last fifty years. The figures in Darwin's large work on the "Variation of Animals" were all drawn from birds selected by myself as the most typical specimens of the various races, but I may state that there is not a single figure shown that would not now be repudiated as utterly unworthy of exhibition by the present fanciers, every variety having had its fancy points so greatly increased. To take the figure of the Spanish fowl (shown in chapter vii.), characterised by its white face and large white ear lobe. This represents a fowl which now hardly exists, for the comb has been increased to at least four times the area of that shown by Darwin; the white skin on the face has been so much enlarged as to cause the birds when aged to become

blind unless the skin is cut away. The ear lobe, enlarged in the portrait to many times its natural size, has been again increased, becoming in some cases more than seven inches in length by four or five in breadth when spread out, and offering an area of some thirty square inches. These characters have been carried to such an excess that the breed has become altered from an abundant layer of large eggs into a practically useless variety, and at many shows where they were formerly the most numerous birds exhibited they are now absent, having been, as it were, improved by the fanciers almost out of existence, their laying qualities and utility having almost entirely disappeared. At the Crystal Palace show recently held, where nearly 4000 fowls were exhibited, less than a dozen Spanish put in an appearance, and at the show just opened at the Alexandra Palace, where there are no less than 281 classes for the different varieties of fowls, Spanish are conspicuous by their absence.

Darwin in his list enumerates thirteen varieties of fowls as known to him, namely Game, Malay, Cochin, Dorking, Spanish, Hamburg, Polish, Bantam, Rumpless, Creepers, Frizzled, Silky and Sooties, with their sub-breeds, which he also mentions. In the last Crystal Palace show we had no less than 240 classes, which included all the varieties shown. The old English Dorking breed was the one which has been least changed or modified during the last fifty years, having been merely increased in size. Cochins, which were imported, not, as the name implies, from Cochin China, but from Shanghai, many hundred miles distant, were originally characterised by profuse fluffy plumage, very small wings, which rendered them almost incapable of flight, a small amount of feather on the tarsus or scaly part of the leg and on the foot. This breed, with all the others, was regarded by Darwin as descended from one wild species, the jungle fowl, *Gallus ferrugineus*. This was one of the very few points in which I differed from my honoured master. I believe that the Cochin descended from another species of wild Gallus, which in consequence of its scant power of flight had all passed into a state of domestication and which has long ceased to exist as a wild bird. My opinions are based upon the fact that there is considerable structural difference between the Cochin and the varieties of the *Gallus ferrugineus*. In the Cochin, the axis of the occipital foramen is greatly elongated perpendicularly; in the ordinary fowl its long axis is horizontal. In the Cochin, as originally introduced, a deep median furrow is visible down the frontal bone, which is not present in other fowls. These points could not have been produced by artificial selection. Then again, the voice of the bird was utterly distinct from that of any descendants of *Gallus ferrugineus*. The habits of the birds, as originally introduced, were exceedingly distinct from those of our domesticated species. At the present time the Cochin threatens to become as nearly extinct in England as the Spanish, having been bred for fancy points, and the tendency to produce feather on the lower extremities has been so enormously exaggerated that in prize specimens the feet are as nearly full plumaged as the wings.

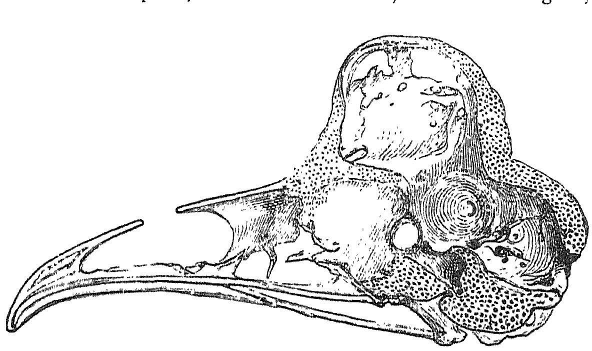

FIG. 1.—Section of skull of crested fowl.

In Darwin's time one of the most remarkable breeds raised by fanciers was the crested, or, as they were then called, the Polish breeds, characterised by a very large tuft of feathers on the top of the head. I paid much attention to these breeds from the singular anatomical peculiarity which they offered; the cranium became greatly modified, the crest taking its rise from a very large bony protuberance of the frontal bones. This in well-developed specimens contained more than half the brain, which, instead of retaining its normal form, became of an hour-glass shape. Specimens of these remarkable skulls were shown by me at the Zoological Society in 1856, figured by Darwin in "Variation" and in my "Poultry Book," from which the accompanying engraving is reproduced. These birds have almost gone out of fashion, there being now no classes for them at the Crystal or Alexandra Palace shows.

If we compare the varieties of poultry as shown at present with those that existed in Darwin's time, we find that the offer of prizes, often of great value, at poultry shows, has induced, not only the formation of innumerable new breeds obtained by crossing and selection, but has led to the exaggeration of the salient points of every variety, as far as is actually possible. If I may presume to quote my own book, on "Table and Market Poultry," I would state: "The fancier has not even a standard of beauty which he regards as final. The greater the extent to which he can make the specimens he produces excel others in fancy points is the object at which he aims; consequently hideous monstrosities are not unfrequently produced and exhibited, the only advantage of which, from a scientific or practical point of view, is to prove the extent to which living organisms are variable under the influence of artificial as opposed to natural selection." W. B. TEGETMEIER.

FRESH LIGHT ON THE ANTARCTIC.[1]

THIS is the second narrative of the cruise of the *Southern Cross* and of the first winter spent on Antarctic land. It is written for the same class of the general public as its predecessor by the commander of the expedition. Mr. Bernacchi is, however, a man of scientific training, and although the exuberance of his literary style is sometimes in excess of the strict requirements of science and some of his words do not occur in the dictionary, we are able to gather a few new facts and some corrected impressions from his book. Unfortunately, the book has been written in a hurry, for which there is at least the excuse that the author has set out once more to the South Polar regions; but in one place he acknowledges, and in many places leaves it to be discovered, that he was unable to consult his companions on points that require some explanation.

It is not everyone who can write a book so as to exclude the irrelevant and make the essential attractive to the average reader; yet this, we think, should be the chief justification of a narrative, and especially a second narrative, of an expedition that was in a considerable degree scientific.

The book is divided into two parts, "Narrative" and "Scientific." The narrative need only be referred to in order to remind the reader of the necessary dates which are usually difficult to gather in such works. The *Southern Cross* left London on August 22, 1898, reached Madeira on September 4, left on the 5th, touched at St. Cruz on

[1] "To the South Polar Regions. Expedition of 1898–1900." By Louis Bernacchi, F.R.G.S. Illustrated from photographs taken by the author. Pp. xvi + 348. (London: Hurst and Blackett, Ltd., 1901.) Price 12s. net.

the 7th, stayed a day at St. Vincent (date not given), reached Tasmania on November 27, ninety-seven days out from London, and sailed on December 19 for the Antarctic regions. The ice-pack was entered on December 31, the Balleny and Russel Islands were seen while fast in it, and on February 10, 1899, the ship, having been unable to penetrate the belt of ice, came out again on the northern side. She entered it once more on the 14th, got through in six hours, and reached Cape Adare on the 17th. On March 1 the ship left for Australia after landing the expedition, and on January 28, 1900, she returned; but no particulars are given, either here or in Mr. Borchgrevink's book, of her two voyages through the pack. On February 2 the whole party started southward in the ship; they landed on Possession Island, in Wood Bay, at the foot of Mount Melbourne, on Franklin Island on February 10, at Cape Crozier, close under Mount Terror, and finally upon the ice-barrier itself in 78° 34′ S. on the 17th. The ship remained moored to the ice-barrier all day on the 18th, and on February 19 the return voyage began along nearly the same route as had been taken coming south. The weather was very boisterous, and the remarkable fact is now stated, we believe for the first time, that no ice whatever was met with and there was absolutely no pack to go through. Auckland Island was reached on March 21, 1900, and here the expedition may be said to have completed its labours. It would have been highly important if the log of the *Southern Cross* were published in full, so that there might be no uncertainty as to the exact dates of reaching the various points, and in particular as to the condition of the sea-ice.

Mr. Bernacchi very clearly indicates the character of the Antarctic summer, a period of low temperature and high wind, with very frequent fogs and rare intervals of clear weather. He states definitely that Mount Erebus was never clearly visible, merely a glimpse having been had of it, too short to allow a photograph to be taken. On February 19 the ship as she lay at the ice-barrier was beset with young ice, and broke through with such difficulty that another day's delay would have meant another year.

The specially "scientific" part of the book is an appendix, though not so called, of 50 pages. It treats of the climate of the South Polar regions, terrestrial magnetism, zoology, geology, astronomy, and concludes with miscellaneous notes and a short glossary of ice-terms.

In discussing the climate, Mr. Bernacchi founds his remarks on a preliminary study of the observations taken at Cape Adare, which have been discussed at the Meteorological Office and are to be published by the Royal Society. The winter was not nearly so cold as at continental stations within the polar circle in the northern hemisphere, the absolute minimum recorded being $-43^{\circ}\cdot 5$ F. and the mean minimum of the coldest month, August, $-22^{\circ}\cdot 7$ F. On the other hand, the summer is very cold, the absolute maximum being $48^{\circ}\cdot 7$ and the mean maximum of January (the warmest month, apparently, although there are no values for February) $37^{\circ}\cdot 0$; the mean temperature of this midsummer month was only 33°, and the absolute minimum 25° F., but a short distance further south minima below zero Fahrenheit were observed early in February. The most remarkable feature, however, was the wind. Windroses are given for each month of the year, showing that the south-eastern quadrant of the horizon has an immense preponderance of winds in every month and a monopoly of gales. This is assumed as strong evidence of the existence of a great continental anti-

FIG. 1.—The Slate Formation in Robertson Bay. (From "To the South Polar Regions," by L. Bernacchi.)

cyclone to the south; and no doubt that theory is attractive and has much evidence in its favour. But the gales which burst from the E.S.E. or S.E. were invariably accompanied by a sudden and great rise of temperature, which in eleven cases cited ranged from nearly 14 to more than 44 Fahrenheit degrees. This wind beat against Cape Adare from the level surface of the frozen sea, and does not suggest a Föhn effect or an origin in the icy heart of a South-Polar anticyclone. Does it not rather indicate the passage of a cyclone centre to the north and the sweeping in of air from the warm surface of the sea south of Australia? An anticyclone brooding over the southern land would probably tend to turn wandering cyclones eastward along its margin, and the two explanations are thus to some extent compatible.

The magnetic observations are being worked up by Dr. Chree; from the preliminary figures quoted here we note that the greatest dip observed was 88° 2′ 37″ at the base of the Mount Melbourne, but it is pointed out that the magnetic dip all along the coast of Victoria land was less than at the time of Ross's expedition. The zoological chapter contains no information; it merely quotes a few descriptive remarks of the vertebrates noticed, all of them of known species. The invertebrates are not referred to, but the whole of the zoology of the expedition is being worked up at the British Museum.

There was no geologist on board the *Southern Cross*, but the non-technical descriptions of rocks in the narrative and the reference to the determination of specimens by Mr. J. T. Prior show that the geologist on the *Discovery* will have a splendid field in which to win his spurs, though the alternation of volcanic and metamorphic rocks does not suggest the probability of sensational fossil finds.

The difficulty of making astronomical observations in high southern latitudes is feelingly dealt with. The determination of longitude was particularly difficult, the only really satisfactory attempt to fix Cape Adare being by an occultation of Saturn by the moon. Refraction was a never-ceasing trouble, for the horizon was frequently very far from being a straight line. Thus on one occasion Mr. Bernacchi says (p. 156):—

"Huge icebergs to the north which must have been quite thirty miles away, and which, under ordinary circumstances, were invisible even from the huts, were elevated by refraction to a height on a level with the top of Cape Adare, the height of which is nearly 900 feet. The display, it can almost be called so, was ever changing in appearance; sometimes one part of the horizon was elevated, then this would subside and another part rise up. At this time of the year the coast line in the direction of Yule Bay and Cape North, nearly 100 miles away, was frequently seen on clear days in consequence of the great rarity of the atmosphere."

A comparison of Mr. Borchgrevink's and Mr. Bernacchi's narratives yields several minor points of interest to which it is unnecessary to refer; but we find the resultant of reading both books is an increase of our opinion of the commander's power of overcoming difficulties and of the physicist's scientific zeal and loyal cooperation.

THE SPECTRA OF BRIGHT SOUTHERN STARS.[1]

THE well-known researches on stellar spectra which have been carried on for many years at the Harvard College Observatory under the direction of Prof. E. C. Pickering have now reached another very definite stage. The publication of the Draper Catalogue in 1890 put us in possession of the general characteristics of the spectra of more than 10,000 stars, and this work will long remain a monument to the skill of Prof. Pickering, besides fulfilling its original purpose as a lasting memorial of Dr. Henry Draper (NATURE, vol. xlv. p. 427). Following this, a detailed description and classification of the spectra of 681 of the brighter stars north of −30°, based upon photographs taken with relatively large dispersion, was published in 1897 (NATURE, vol. lvi. p. 206). The establishment of a branch observatory in the southern hemisphere, at Arequipa, Peru, has enabled Prof. Pickering to extend the inquiry to the southern stars, with results described in the volume under notice.

The prismatic camera has been employed throughout the whole investigation, and the accumulation of so much valuable material in so short a time must be attributed in great measure to the many advantages which this instrument possesses over the slit spectroscope when radial velocities are not in question. At Arequipa the 13-inch Boyden telescope has been employed in conjunction with one, two or three prisms, giving spectra of lengths 2·24, 4·86 and 7·43 centimetres respectively from $H\epsilon$ to $H\beta$. The number of photographs taken from November 29, 1891, to December 6, 1899, was no less than 5961, with an average exposure of one hour; but as many of the spectra were photographed several times the number of individual stars investigated is smaller, namely 1122. In these are included all stars south of declination −30° which have a photometric magnitude of 5·0 or brighter, numerous fainter stars in the same region, many stars between the equator and −30°, and a few northern stars.

Dr. McClean's magnificent series of photographs of the spectra of southern stars had prepared us to find that the spectra are not less diverse than in the northern hemisphere, and it became a point of much interest to see if the greater number of stars now studied necessitated any revision of the classification proposed for the northern stars alone. This question of classification, it will be understood, is one of the greatest importance, since the ultimate aim is not merely to enable the astronomer to place his photographs in their proper pigeon-holes, but to indicate the various stages of star life. It is an unfortunate circumstance, however, that not one of the classifications hitherto suggested has met with general acceptance, but the reason for this may perhaps be traced to a want of confidence due to the frequent revisions which have been necessary as the more delicate features of the spectra have been brought to light by the use of better instruments. However that may be, it is sufficiently remarkable that the old classification which we owe to Rutherfurd and Secchi is almost the only approach to a universal language of stellar spectra, in spite of the fact that it is hopelessly inadequate to deal with modern data.

For the present discussion Miss Cannon has found it convenient to revert to the nomenclature of the Draper Catalogue, but with modifications to suit the intermediate classes revealed by the use of greater dispersion. It is pointed out that in most cases the symbols can be readily translated into the numbers previously applied to the groups of northern stars, but it would surely have been more convenient to have two such closely associated investigations expressed in the same language. However, the classification is fairly adequate, but as the nomenclature is too cumbersome to be likely to come into common use it is unnecessary to describe it in detail.

The great majority of the 1122 stars discussed in this publication can be arranged in a sequence, agreeing in the main with that arrived at in the case of the northern stars, but permitting its extension towards the beginning of the series. The investigation of the northern stars led Prof. Pickering and Miss Maury to commence the

[1] "Spectra of Bright Southern Stars, Photographed with the 13-inch Boyden Telescope as a Part of the Henry Draper Memorial, and Discussed by Annie J. Cannon under the Direction of Edward C. Pickering." (*Annals* of the Astronomical Observatory of Harvard College, vol. xxviii. part ii.)

series with stars of the "Orion" type, which by transitional stages were succeeded by the Sirian and solar stars, and then by stars with fluted spectra. An important advance has now been made in establishing the place of the bright-line stars of the Wolf-Rayet class as immediately preceding the stars of the Orion type. The spectra themselves do not indicate whether the series begins or ends with the bright-line stars, but that it begins with them is probable from their general spectroscopic resemblance to nebulæ. One piece of evidence on this point does not seem to have been followed up as closely as its importance calls for; on p. 141 it is stated that the green line λ 5007, which has hitherto been regarded as specially characteristic of nebulæ, is sometimes present in the Wolf-Rayet stars. If this be the case there would seem to be no possible doubt that the bright-line stars are the first results of nebular condensation; but we find no further reference to this interesting point in the detailed description of spectra.

A considerable part of the volume is occupied with detailed accounts of typical spectra which are exceedingly valuable, and the descriptions of the various classes of bright-line stars will be especially welcomed by other investigators. The discussion apparently indicates that the forms most closely resembling the planetary nebulæ are those in which there are no dark lines in the spectra, while succeeding stages are represented by stars in which dark lines are gradually introduced, until finally the Orion type of spectra, usually consisting wholly of dark lines, is reached.

Three catalogues are given. One of them brings together the stars belonging to each of the spectroscopic groups; another is a general catalogue with the stars in order of right ascension; and still another is an index to the stars, both northern and southern, which have letters assigned to them. In the last named, the nomenclature previously employed for the spectra of the northern stars has been converted into the new system adopted for the present volume. It will thus be seen that no pains have been spared to provide every convenience for those who may have occasion to use the catalogues for purposes of reference.

Besides the catalogues there are several tables of the wave-lengths and intensities of the lines in the various sub-groups of the bright-line stars and stars of the Orion type, and in some cases the wave-lengths extend into the visible spectrum as far as D_3. It is only in the more obvious cases, however, that an attempt has been made to assign origins to the lines, but the determination of origins is perhaps wisely avoided unless the work of a laboratory goes hand in hand with that of an observatory. Still, one cannot help regretting that the tables of enhanced lines published by Sir Norman Lockyer have not been utilised in this connection, especially as there are distinct indications that some apparent difficulties might thus have been removed. Thus, on p. 186 it is stated that in the spectrum of α Cygni there are two lines of greater wave-length than H_β, which are "well marked and agree in position and intensity with the helium lines 4922·1 and 5015·7 as present in the spectra of the Orion stars. It appears far more probable, however, that these are solar lines." The probability is that these lines, like so many others in α Cygni, according to Sir Norman Lockyer, are enhanced lines of iron, their wave-lengths being 4924·1 and 5018·6, which are curiously near to two prominent lines of helium. It seems very likely also that a reference to enhanced lines would throw much light upon such spectra as that of η Carinæ (Argûs) and possibly upon other "peculiar" spectra.

Again, the descriptions of typical spectra clearly show that among the first additional lines introduced in passing from the Orion to the Sirian stars are 4233·6, 4173·6, 4179·5 and 4385·2, which are doubtless enhanced lines of iron at corresponding wave-lengths; these lines, however, are simply regarded as "characteristic solar lines" (p. 154), although as the true solar stage is approached they cease to be conspicuous.

Among many interesting results, it may be mentioned that a few stars have been found to have spectra resembling that of α Cygni, which hitherto had been practically the only representative of its type. The detailed description of the spectrum of γ Velorum (Argûs), the brightest star of the Wolf-Rayet type, is also worthy of special mention.

The volume is enriched by three fine plates, one of which illustrates six typical spectra; another shows six examples of "peculiar" spectra, including ζ Puppis and γ Argûs; while the third exhibits, by direct enlargements of portions of three spectra, the vast amount of fine detail portrayed by the prismatic camera.

Great praise is due to all who have taken part in this magnificent piece of work.

A. FOWLER.

FOREIGN INDUSTRIAL COMPETITION AND TECHNICAL EDUCATION.

ON the occasion of the prize distribution to the students of the Goldsmiths' Institute at New Cross, on December 12, Mr. Balfour made some remarks on technical education and its bearing upon foreign competition which are worthy of comment. With the optimism which characterises this statesman's utterances, he expressed the opinion that although

"unquestionably there was a time when we ignored the great need for a thorough scientific and artistic training in connection with our great industries," yet he was "not sure whether we are not now verging upon the opposite danger to that which we ran a few years ago," for there was a tendency, in some quarters at all events, to "talk as if the only thing which had to be done to restore British manufactures to their pristine condition in the world's industries was a manipulation of our methods of education."

Mr. Balfour then went on to say that he placed no faith whatever in the arguments which he constantly heard indicating the relative decay of British manufactures, and deprecated the tendency, which he characterised as a "dangerous fallacy," of supposing

"that every successful and prosperous manufacture started by any other nation but our own was a kind of robbery committed on British trade," for we ought to be satisfied with the reflection that, "broadly speaking, the prosperity of one nation conduces to the prosperity of all nations, and we are not poorer, but richer, because other nations are rich."

As was to be expected, these self-satisfying sentiments met with full approval; but the distinguished speaker proceeded to introduce a little rift into his lute when he said,

"I look with perfect serenity upon the general increase of the world's wealth as long as I can be assured that in this country we organise our labour in such a manner that the best workman gets the greatest remuneration; . . . . that there is no lack of well-trained and skilled persons in all branches of manufacture; and last, but not least, that those who lead industry in this country, the capitalists, the manufacturers and the managers, show that flexibility, that power of adaptation to the ever-changing needs of the world which is, of course, an absolute necessity if we are to make the best of the great advantages by which we have been enabled to meet the demands of the world in the matter of manufacture."

Mr. Balfour is apparently already assured on these points, but can this attitude be accepted by those who view the future of their country from a higher standpoint than that of an armchair political economy? Are we to stand calmly by and see the supremacy in industry after industry transferred to foreign shores until at last, like the inhabitants of a Gilbertian island, we are re-

duced to living by taking in each other's washing? The economical laws which apply to nations are much the same as those which govern individuals, but we have yet to meet the man who takes pleasure in his competitors' wealth on the ground that it conduces to his own prosperity. What is to be gained by burying our heads in the sand and announcing that no danger is in sight? With nations as with individuals, progress must cease when self-complacency begins.

Considering first Mr. Balfour's last proposition—Do the leaders of industry in this country show that flexibility and power of adaptation to changing needs which is absolutely necessary for meeting the demands of the world in manufactures? If we are to credit the statements of experts in almost every branch of trade, and the facts which are patent to our eyes, we must conclude that they do not. In the chemical industries, where, before all others, adaptation to rapid changes and the immediate utilisation of new scientific discoveries are of paramount importance, we have not only lost the supremacy we once possessed, but we stand at present in great danger, in the organic-chemical manufactures at any rate, of falling out of the running altogether. The chemical trade of Germany, built up almost entirely during the last forty years, now amounts to an annual value of about 50,000,000*l.*, of which about 10,000,000*l.* represents the value of the production of colouring-matters, synthetic medicinal agents, perfumes, and other coal-tar products. If we examine in detail the statistics of this latter branch, we find that the six largest German manufacturers alone employ more than 18,000 workpeople, 500 chemists, 350 engineers and technologists, and 1360 business men, managers, travellers, clerks, &c. In England, the birthplace and cradle of this industry, there are certainly not more than 30 or 40 chemists and 1000 workpeople employed upon it, and whilst our imports of colouring-matters have slowly increased, our exports to the world of these products, which, fifteen years ago, amounted to about one-fourth of those of Germany, do not now amount to a tenth part. Even in the home market we are only able to supply about ten per cent. of the total quantity of dye-stuffs our textile industries require. In the manufacture of synthetic medicinal agents, artificial perfumes, sweetening materials, photographic developers, &c., which are all outgrowths of the coal-tar colour industry, the matter is even worse, for these manufactures are almost non-existent in this country. Even in the "heavy chemical" trade, which has always been regarded as one of our staple industries, we find ourselves seriously assailed, and most of the important developments of recent years have taken place upon the Continent. We further stand in imminent danger of losing nearly three millions annually by the destruction of our Indian indigo industry in competition with the synthetically prepared indigo of Germany, because the study of organic chemistry has been so much neglected in this country that we have neither attempted to improve (until quite recently) the crude and wasteful methods of obtaining the natural indigo, nor devoted ourselves to discovering methods for its artificial production. Is it conceivable that an English firm of chemical manufacturers would be willing to devote, as the Badische Company have done, nearly a million pounds to experimental plant, and scientific investigations extending over twenty years, in an enterprise of this character?

If, again, we turn to the engineering industries, in which a pre-eminence may fairly be considered our birthright, we meet with a somewhat similar state of affairs. In electrical engineering it is universally recognised that we must now concede the palm to America. Also in tool-making machinery, printing machinery, type-writers, &c., the American manufacturers are able to turn out better and cheaper work than our own. In machinery for chemical processes Germany has established a speciality, whilst in the building of motor-cars—a very large and profitable industry directly developed out of the cycle industry—France by her superior workmanship has been able to obtain a monopoly. We are also outstripped by France in all those industries in which the native artistic taste of the workman plays an important part.

Although it could not, of course, be expected that we should excel in every branch of manufacture, can we consider, with such facts as these before us, that our leaders of industry show the requisite adaptability to modern conditions to which Mr. Balfour refers? or, in other words, are they sufficiently alive to the importance of applying science to industry in every branch of manufacture? Further, are we justified in saying "that there is no lack of well-trained and skilled persons in all branches of manufacture"? Are our technical schools, as Mr. Balfour appears to believe, turning out the men who will reinstate our lost or declining industries? Much as we may appreciate the excellent work which these institutions are doing for the general education of the masses, we are forced to the sorrowful conclusion that this is not so, and that so far as higher scientific education is concerned the results are far out of proportion to the enormous sums which have been devoted to their establishment. The fault for this in no way lies with the technical schools themselves, but with the want of system and incompleteness of our national education. In place of putting a coping-stone of technical knowledge upon an already sound and thorough education, these institutions are more often called upon to cram the elements of a science, or, worse, the details of its industrial application, within a minimum of time into the minds of school-boys or lads engaged in technical pursuits, who, through absence of a satisfactory educational foundation, are quite unfitted for their reception. The result too often is the entire extinction of any natural originality which the lad might have possessed, and the conversion of his mind into a machine for the unthinking performance of routine operations. How is it possible, for instance, that a chemist who, after a very insufficient general education, has acquired his knowledge of the science by a two or three years' course of study at a technical school, should equal in capacity his German colleague, who, upon the basis of a sound school education, has received a five years' training at a German University or Polytechnicum, where he has not only acquired a thorough grasp of his own and cognate sciences, but by carrying out investigations has been stimulated in originality and encouraged to seek new knowledge for himself? Except in the rare instances where native genius is bound to come to the fore, the former can have no possible chance in competition with the latter. It is even a matter of but little moment whether the education of the German has embraced any technical instruction, as with the sound knowledge he possesses of the principles of his science he will soon learn in actual practice their technical applications, and when learnt can usually carry them much further. That nearly all the best positions of the chemical profession in this country are at present filled by German chemists, or by English chemists educated in Germany, is the best proof of the inferiority of our educational methods.

What we undoubtedly require is what Mr. Balfour satirically calls "a manipulation of our methods of education." We require a "system" in the educational fabric of the country, which, together with a better appreciation of the value of science in every industry, would do much to enable our technical schools to fulfil their proper function and to carry out the work which the country expects of them. That such a reform of our educational methods may be long in coming we may, however, well believe, when we hear a distinguished statesman and leader of philosophical thought fail so entirely to appreciate the needs of the case. ARTHUR G. GREEN.

NOTES.

MESSAGES from Newfoundland announce that Mr. Marconi has succeeded in signalling from England to America by wireless telegraph. Detailed information is not yet available, but it is said that the signals which were received at St. John's, three on Thursday and one on Friday last, though faint were unmistakable, and that Mr. Marconi intends to come immediately to England to increase the power of his transmitters at Poldhu, Cornwall, in order to establish more satisfactory communication across the Atlantic. According to later information the Anglo-American Telegraph Company have given Mr. Marconi notice to remove his instruments from the Colony, as they possess a fifty years' telegraphic monopoly, of which there are still two years to run. This will involve the removal of his experimental station to Nova Scotia or to some other convenient place on the American coast line, and may, perhaps, somewhat delay further experiments. It is to be hoped, however, that we shall before long see a further development of Mr. Marconi's remarkable achievement, upon which if confirmed by subsequent results he cannot be too warmly congratulated. It is interesting to compare the possible rapid development of wireless telegraphy in Mr. Marconi's hands with that of the ordinary telegraph. The first Atlantic cable was not laid until five-and-twenty years after the invention of the telegraph by Gauss and Weber. The earliest proposal to use Hertz waves for signalling was made in 1891, and Mr. Marconi began his experiments four or five years later; at that time he was able to signal two or three miles, and now, after five years' work, he claims to have succeeded in increasing this distance a thousandfold.

GEOLOGISTS and geographers will be glad to learn that they may soon expect the publication of a new map of Iceland on which Mr. Thoroddsen, whose labours in his native island are so well known, has been engaged for twenty years. It is on a scale of 1/600,000, or about twenty English miles to the inch, and thus affords at a glance an excellent picture of the general physical structure and geological characters of the country. But it is also replete with details which are expressed in symbols that take up little space and are readily intelligible. The map, of which we have seen a proof copy, is excellently engraved and printed in colours at Copenhagen, and will be issued under the auspices of the Carlsberg Fund. The title and table of signs and colours are in English.

CONVINCED that increased knowledge of the methods of education on the Continent and in America, with special regard to their bearing on questions of commerce and industry, is required in England, Mr. Alfred Mosely, C.M.G., has offered to defray the whole expense of a commission of inquiry, which would visit parts of the Continent and of America to study the question. At a meeting held on Monday, under the presidency of Lord Reay, Chairman of the London School Board, to confer with Mr. Mosely, it was decided that the inquiry should take place in the autumn of 1902. It is understood that the promoters of the inquiry will endeavour to secure the co-operation of a number of public men representing various types of educational authorities and also the interests of industry and commerce.

THE full text of President Roosevelt's message to the U.S. Senate and House of Representatives has now been received, and we are glad to notice that it contains the following references to the valuable assistance given by the Smithsonian Institution to scientific progress:—"The advancement of the highest interests of national science and learning and the custody of objects of art and of the valuable results of scientific expeditions conducted by the United States have been committed to the Smithsonian Institution. In furtherance of its declared purpose —for the 'increase and diffusion of knowledge among men'—the Congress has from time to time given it other important functions. Such trusts have been executed by the Institution with notable fidelity. There should be no halt in the work of the Institution, in accordance with the plans which its secretary has presented, for the preservation of the vanishing races of great North American animals in the National Zoological Park. The urgent needs of the National Museum are recommended to the favourable consideration of the Congress."

THE Imperial Leopold Caroline Academy of Science at Halle will celebrate the one hundred and fiftieth anniversary of its foundation on January 1, 1902.

THE first meeting of the Royal Geographical Society in the new year will be held on the afternoon of January 8, when Dr. Vaughan Cornish will give a lecture on "Waves," adapted to young people. At the ordinary meeting on January 13 Dr. Logan Jack will give an account of his recent expedition from Shanghai to Bhamo, and on January 27 Mr. Stanley Gardiner will lecture on the Maldive Islands.

THE council of the Institution of Mining and Metallurgy announce that a gold medal and premium of the value of fifty guineas, presented by the Consolidated Gold Fields of South Africa, Limited, will be awarded annually to the author of the paper of highest merit contributed to the *Transactions* by any member, associate, or student of the Institution, during the preceding session, upon the mining, treatment, or reduction of gold ores. The first award will be made in June, 1902, and succeeding awards in June in each year.

AN exhibition of burners and appliances connected with the use of gas for illumination and other purposes was opened at the Crystal Palace on Saturday. A development of the Welsbach incandescent light is the inverted burner, on which the cone is fixed in a downward position. It consists of a Bunsen burner fitted with a regulator for the supply of gas and attached to a cone of white china, which acts both as a radiator and as a reflector. Hitherto the difficulty has been to get the Bunsen burner to burn downwards on account of its liability to strike back. This difficulty the manufacturers of the burner claim to have overcome. The construction of the burner, with the globe fixed, closely resembles in appearance the hanging globe of the electric light, and, as there is nothing below the light, no shadow is thrown. A new invention in street lamps is exhibited. This is a high-pressure lamp for burning ordinary gas by the method of a self-intensifying action of combustion, and is said to produce a light of from 300 to 500 candle-power from one burner. There are two stands in the show which exhibit the acetylene light. These are interesting on account of the use which is now being made of that gas, not only for motor-car lights, but also for the illumination of omnibuses in London.

AN exhibition of electrical appliances was opened at the Royal Aquarium on Monday. The exhibits include many ingenious electrical instruments and accessories, such as switchboards, electrical heating and cooking devices, generators, accumulators, Röntgen-ray outfits, lamps, electric clocks, anemometers and electric meters. Mr. W. Langdon, the president of the Institution of Electrical Engineers, who was to have performed the opening ceremony, was unable to be present, owing to his work in connection with the interruption of the telegraphs by the recent gale, but he sent a statement, in the course of which he said that exhibitions were performing good educational work, because they gave the manufacturer an opportunity of bringing his achievements before the public and those interested in their use, and enabled the visitor to obtain a more complete knowledge of the use of what was to be seen. If

England was to compete with other nations in the markets of the world, it was necessary that we should not only foster all our resources, but should also endeavour to see that our merchants and manufacturers were placed in as favourable a position to do so as were those of other nations. President Roosevelt had shown how fully he appreciated the fact that the supremacy of a nation, or, rather, its position in national life, would in future depend upon its commercial success. It would be a great advantage to the producer if he could be placed in possession of information relating to the progress of other lands. This had been recognised by the President of the United States, and they could not help hoping that our own Government would have no hesitation in following his example and promptly establishing a Ministry of Commerce and Manufacture to watch over those all-important branches of our national life.

THE Göttingen Academy of Sciences has decided to establish and maintain at its own expense, during the period of the special international magnetic work, a magnetic observatory near Apia, in the Samoan Islands. The observatory, says *Science*, will be equipped for observations in terrestrial magnetism, atmospheric electricity, meteorology and seismology. This observatory will be nearly magnetically south of the Honolulu observatory, and about the same distance south of the magnetic equator as the latter is north of it. The two observatories will likewise use practically the same instruments and methods, so that interesting and valuable contributions may be expected from them. Mr. A. Nippoldt, of the Potsdam Observatory, will be in charge of the Samoan Observatory.

MR. H. N. RIDLEY, Director of the Botanic Gardens, Singapore, delivered a lecture at the Imperial Institute on Monday entitled "The Economic Resources of the Straits Settlements and the Malay Peninsula." He remarked that the forests, which originally covered the whole peninsula, contain many valuable products, such as timbers, wood-oil, benzoin, gutta-percha and rattans. Owing to the felling of trees by the Malays, gutta-percha, so indispensable for electric work, has been nearly exterminated. Fortunately, however, the product can now be extracted from the leaves and twigs without injury to the trees, which are being planted by the Government. A very large area of the Federated States is under coffee, but on account of the present glut of the market and the consequent low prices, most of the planters are adding Para-rubber to their estates—a tree which thrives marvellously well and produces a very satisfactory amount of rubber of the first quality. India-rubber from the *Ficus elastica* also promises well, but although it is being planted, its product is less highly valued. Accounts were given of the cultivation and preparation of sago—one acre of the sago palm gives as much nourishment as 163 acres of wheat—tapioca, gambir, mangrove-cutch, pepper, nutmegs, cloves, indigo and pineapples. The greater part of the preserved pines of commerce come from Singapore, where the price of the fruit varies from a farthing to a penny each, and the lecturer remembered a time when they had been as cheap as sixteen a penny. The mineral resources of the colony include gold and tin, the latter being found in great abundance.

DURING the past week this country has been visited by disastrous storms, which have caused more interruption to railway and telegraphic communication than has occurred for many years—although in few cases only has the force of a strong gale been reached; the principal damage appears to have been due to the amount and weight of the snowfall. The daily weather reports published by the Meteorological Office show that on the morning of Wednesday, the 11th inst., the barometer was rising generally and that there were no signs of any material change in the weather beyond the fact tha shallow cyclonic areas of a "secondary" character were apparently moving southwards over the northern districts and were likely to occasion snow showers in most parts of the kingdom. But the chart for the next morning showed that a deep cyclonic disturbance had reached our south-west coasts from the Atlantic and was moving in an easterly direction. By Friday morning (13th) communications with many of the northern and north-western stations were completely interrupted. The progress of the storm was rather slow, and the unusual course taken, to the south instead of the north of our islands, brought cold easterly and northerly winds and very heavy snowfall in the north and rainfall in the south. The fall measured at Yarmouth for the twenty-four hours ending 8 a.m. on Friday amounted to two and a half inches (or about the average amount for the month). The loss at sea has not been great, owing, presumably, to timely notice issued to the eastern districts.

SIR CHRISTOPHER FURNESS, M.P., who has recently returned from a business journey through Canada, appears to have been very considerably impressed with the enormous strides that are being made in the development of water-power for manufacturing purposes in that country. On Lake Superior, which is 400 miles long and 160 miles wide, the Lake Superior Power Company, about five or six years ago, commenced operations by constructing a canal from the lake of sufficient capacity to work turbines of 20,000 h.p. This power is used for making pulp for paper from spruce fir, and an area of 8,000,000 acres of forest has been obtained for supplying the wood by grant from the Dominion Government and by purchase. The Algona Iron and Steel Works have also been established; besides the nickel ore which is being worked, a large find of iron, said to be practically limitless, has been located. Large Bessemer steel works for the manufacture of steel rails, capable of turning out 1000 tons of steel rails a day, are expected to be in operation at the beginning of the new year. In these works electricity has been almost entirely adopted for applying the power to the machinery. Further works for developing 40,000 h.p. are in progress and expected to be completed in about a year and a half.

THE equations of rational dynamics required for the solution of physical problems involve only one independent variable, namely the time. Dr. Leo Königsberger, of Heidelberg, has communicated to the Berlin *Sitzungsberichte* a paper dealing with the extension of the Lagrangian equations to systems involving any number of independent variables, in which the kinetic potential is of the most general possible form. In the present paper Dr. Königsberger treats in detail the case of two independent variables, where the kinetic potential involves only differential coefficients of the first order. The author thus formulates a dynamics of two-dimensional, or n-dimensional, *time*, analogous to the geometry of n-dimensional space. Among the most interesting results are those dealing with the conditions under which the principle of conservation of energy holds for two or more independent variables. In the case of two variables it appears that a certain condition must be satisfied in order that an infinite number of integrals of the Lagrangian equations of motion may exist which satisfy the principle of energy, but it is no longer the case that all integrals satisfy the principle in question. A special case is that in which there is only one *dependent* variable; here the equation of energy is always an integral of the equations of motion.

GEOLOGY and meteorology formed the subject of a brief article in NATURE for November 14. Since then an important essay has been issued on the distribution of vertebrate animals in India, Ceylon, and Burma, by Dr. W. T. Blanford (*Phil. Trans.* 1901), who finds that certain peculiarities in the Indian

fauna may have been due to the Glacial epoch. Ancient terminal moraines occur at an elevation of about 7000 feet in Sikhim, whereas no glacier at the present day is known to descend much below 14,000 feet. The author's observations, moreover, lead him to conclude that the Glacial epoch affected the whole world, and that it was not a partial phenomenon induced by special conditions, such as local elevation.

MR. GEORGE ABBOTT, of Tunbridge Wells, has printed a classified list of the "Cellular" Magnesian Limestone Concretions found in the Permian formation of Sunderland. These concretions are grouped as pseudo-organic or discoid, coralloid, and honeycomb, and are considered by Mr. Abbott to have originated in a different way from the botryoidal masses. He illustrates four stages in each group, remarking that the structures have been produced by the action of a "molecular directive force." As a contribution to the study of "concretionary action" the diagrams should prove useful, but some particulars are desirable with regard to the conditions under which the different groups occur.

IN a letter to the *Centralblatt für Mineralogie* (1901, No. 21, p. 641) Dr. Berwerth, of Vienna, discusses the structure of chondritic meteorites. It will be remembered that according to one view the structure is that of a tuff and the stone is the product of a celestial volcano; according to another view, the structure, though fragmental, is not that of a tuff, but the result of the sudden cooling of a molten mass; according to a third view the chondritic structure is that of a metamorphic rock and may be really of a terrestrial origin, having possibly resulted from the enormous pressure on the stone during its passage through the earth's atmosphere. After a minute petrographical study of the Zavid meteorite, Dr. Berwerth infers that the structure of a chondritic stone is that of a metamorphosed volcanic tuff, and that the metamorphosis has been due, not to great pressure, but to a partial remelting of the material, through exposure of the stone to great heat, followed by quick cooling. The author points out that there may have been a sudden development of heat while the tuff was *in situ*, for instance, through the birth of a new and neighbouring star, or, again, that the stone may have passed through the upper region of a sun's atmosphere during part of its celestial journey.

AMONG a number of papers in the recent issue of the *Proceedings* of the Philadelphia Academy, attention may be directed to one by Mr. H. A. Pilsbry on the Clausilias of the Liu-Kiu (Loo Choo) Islands. A large number of these land-shells are recorded, many of which are new; for one group a new subgeneric term is proposed. A second paper, by A. M. Fielde, describes in detail the life-history of the ant known as *Stenamma fulvum*. The observations were made, for the most part, on colonies kept in portable nests, of which a description is given in No. 2 of the second volume of the *Biological Bulletin*.

THE first annual general report has been published (1900–1901) of the newly formed Department of Agriculture and Technical Instruction for Ireland, wherein the scope and constitution of that body are defined. The Dublin Science and Art Museum now comes under the cognisance of the Department, and the report of the director is included in the volume before us. It is satisfactory to learn that the Museum is making steady progress in all its sections. Among several interesting additions to the zoological collections during the year, "by far the most important was Ussher's collection of Irish birds' eggs, contained among which are many which have now become rare and practically unobtainable. For the purpose of showing the wide range of variation in clutches such as those of the peregrine falcon, the guillemot and others, Mr. Ussher's collection is unequalled and invaluable." The director adds that his permanent staff is not sufficiently large to allow him to make all the improvements in the arrangement of the Museum he thinks desirable.

A NEW illustrated catalogue of apparatus for laboratory experiments and lecture demonstrations in frictional and voltaic electricity has been published by Messrs. C. E. Müller, Orme and Co. It is evident from the catalogue that scientific apparatus can now be obtained at a much lower price than formerly.

A WORK on "British Vegetable Galls, an Introduction to their Study, Collection, Mounting, Classification, &c.," by Mr. Edward T. Connold, will be published immediately by Messrs. Hutchinson and Co. The volume will contain numerous illustrations reproduced from photographs of living specimens of vegetable galls.

THE *Electrical Review* devotes practically the whole of its last week's issue (December 13) to electric traction work. The number contains articles by such well-known traction experts as Messrs. Philip Dauson and F. J. Sprague, and also many excellent descriptions and illustrations of machinery and appliances used in traction work, which make it of great value to those engaged or interested in this branch of engineering.

THE first part of a work on "The Fauna and Geography of the Maldive and Laccadive Archipelagoes," by Mr. J. Stanley Gardiner, was published a few weeks ago by the Cambridge University Press. Mr. Gardiner left England in 1899 as Balfour Student of the University of Cambridge, with a commission to explore and investigate the coral reefs of the Laccadives, Maldives and Ceylon. The results of the expedition will be described in the work now in course of publication. The second part of vol. i. will be published in April next, and when the work has been completed it will be reviewed.

MEMBERS of the British Association are well aware that excellent manuals upon scientific aspects of the places of meeting are prepared under the direction of the Local Committees. In connection with the meeting at Glasgow three volumes of this kind were prepared, and as copies have been sent to us since the conclusion of the meeting we presume they are still available. The subjects are:—"Fauna, Flora and Geology of the Clyde Area," edited by Messrs. G. F. Scott Elliot, Malcolm Laurie and J. Barclay Murdoch; "Local Industries of Glasgow and the West of Scotland," edited by Mr. Angus McClean; and "Handbook of Archæology, Education, Medical and Charitable Institutions," edited by Prof. Magnus Maclean. The volumes are filled with trustworthy information upon matters of scientific and engineering interest, and deserve to be widely known. Though published particularly for the meeting of the British Association, probably copies can still be obtained from Glasgow booksellers, or the acting secretary of the Local Committee, Mr. John S. Samuel, 30 George Square, Glasgow.

THE additions to the Zoological Society's Gardens during the past week include a Lesser White-nosed Monkey (*Cercopithecus petaurista*) from West Africa, presented by Mrs. K. Harris; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Captain R. J. Vyner; a Rhesus Monkey (*Macacus rhesus*) from India, presented by Miss Rodel; a Marica Gazelle (*Gazella marica*) from Arabia, presented by Mr. F. C. Strick; a Common Otter (*Lutra vulgaris*) from Scotland, presented by Mr. W. Radcliffe Saunders; a Plantain Squirrel (*Sciurus plantani*) from Java, presented by Mrs. Beauchant; two South Island Robins (*Miro albifrons*) from New Zealand, deposited; a Nicobar Pigeon (*Calaenas nicobarica*) from the Indian Archipelago, purchased: five Shaw's Gerbilles (*Gerbillus shawi*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

AN ASTEROID-ORBIT OF GREAT ECCENTRICITY.—Prof. E. C. Pickering announces that from an examination of a plate taken on August 14, 1901, with the Bruce telescope, Dr. Stewart found an asteroid having the great southern declination, $-62°$. Fourteen photographs were taken up to November 13, furnishing approximate positions for the computation of the orbit. A circular orbit was first calculated, which gave the surprising result that the heliocentric diurnal motion exceeded 2200″, indicating a distance from the sun less than that of any known asteroid. Prof. Newcomb furnishes the following elements :—

Epoch 1901, October 2·627 G.M.T.

$$\left.\begin{array}{l} M = 358°\ 30' \\ \omega = 301\ 19 \\ \Omega = 35\ 48 \\ i = 18\ 38 \end{array}\right\} 1900.0 \qquad \begin{array}{l} \phi = 22°\ 8' \\ \mu = 860'' \\ \log a = 0·4103 \\ \text{Period} = 4·13 \text{ years.} \end{array}$$

The uncertainty of the elements ω and Ω may be about $\pm 1°$. It would thus appear that the ellipticity of this new planet is in considerable excess over that of any previously known asteroid. The only others for which ϕ exceeds 20° are :—

	° ′
Eva (164)	20 19
Istria (183)	20 27

The new asteroid was near perihelion at the time of its discovery, moving rapidly round the sun at a distance of about 1·6. It is rapidly moving north, and will soon be available for observation from northern observatories, as shown by the following approximate ephemeris for Greenwich midnight :—

BRIGHT METEOR OF DECEMBER 16.—An exceedingly brilliant meteor was observed at South Kensington on the evening of Monday, December 16, about 6·45 p.m. Starting from near α Persei, about 60° elevation, it travelled in a northerly direction inclining downwards until, after a path of about 30°, it disappeared beneath the Pole star. The meteor was two or three times brighter than Capella, and appeared of a similar tawny yellow colour, although this might have been mainly due to the slight fog prevailing at the time. The trajectory was practically rectilinear and the movement very slow.

THE INERT CONSTITUENTS OF THE ATMOSPHERE.[1]

THE discovery of an element always awakens interest; for the total number of the known elements does not exceed seventy-five, and all the various forms of matter which exist on this globe are necessarily composed of these elements.

Elements must not be regarded as isolated entities, each self-dependent, having no relations with its compeers; on the contrary, all the elements exhibit certain connections with their neighbours; and there is to be traced an orderly progression from one class of elements, strongly electro-positive in character, metallic in appearance, very inflammable when heated in the air, and at once attacked by water, to another class, highly electro-negative, transparent, unattackable by oxygen, and without perceptible action on water, through a number of connecting links, each of which serves to soften the transition.

These elements have been arranged in series, and it is by considering the method of arrangement that our interest is awakened.

The revival of the hypothesis of the atomic constitution of matter by Dalton and of his attempt to determine the atomic weights of the elements was not long in provoking the guess that perhaps there could be found some connection between the numbers representing the relative atomic weights of kindred elements. But, as is well known, the state of knowledge in Dalton's day was not sufficiently advanced to enable him to attribute to elements their correct relative atomic weights; and it was not until the eminent professor of chemistry in Rome, Cannizzaro, whose jubilee has recently been celebrated, pointed out the bearing on Dalton's numbers of all the facts accumulated up to the year 1856 that the close relationship between the atomic weights and the properties of the elements was suggested by John Newlands. Some years later Lothar Meyer and Dmitri Mendeléef amplified and elaborated the ideas which had first been propounded by Newlands; and the periodicity of the atomic weights and the gradual variation of the properties of the elements and their compounds were established on a firm basis.

The division of the elements into metals and non-metals corresponds broadly with another well-marked division—that into basic and acidic. Generally speaking, it is the oxides of the metallic elements which react with water to form bases, and those of the non-metals which form acids with water. According to modern ideas, bases, by the mere act of solution in water, are supposed to be split up into portions, for which the term ion, invented by Faraday, has been retained; one ion is charged by the process of solution with a positive charge, and that portion is usually a metal; the other portion, which consists of one or more groups of hydrogen and oxygen in combination, termed "hydroxyl"—OH—has a negative charge. A base, indeed, is a compound which splits in this manner. On the other hand, an acid, when dissolved in water, undergoes an analogous split; but in this case the electro-positive ion is always hydrogen, while the electro-negative ion may either be an element such as chlorine, or a group of elements such as exist in nitric acid (NO_3).

The order of the various elements in the electric series has been determined; and not merely determined, but to each has been attached a numerical value. This value is identical with what is termed "chemical affinity"; and it represents the electric potential of the element with reference to an arbitrary starting-point, which does not differ much from that of nickel, an element closely related to iron. Only a few such values have as yet been determined numerically; instances may be chosen from the magnesium group, where the numbers run: Magnesium = + 1·2; Zinc = + 0·5; Cadmium = + 0·19; or from the fluorine column, where the numbers are: Fluorine = − 2·0; Chlorine = − 1·6; Iodine = − 0·4. In each case the potential, positive or negative, is the highest for the element with smallest atomic weight, and decreases with increase of atomic weight, for elements in the same column. The order of some of the elements is: Cs Rb K Na Li Ba Sr Ca Mg Al Mn Zn Cd Fe″ Co Ni Pb H Cu Ag Hg′Pt‴′ Au′″; and for electro-negative ions, S″ O″ I Br Cl F; the first element, cæsium, being the most electro-positive, and the last, fluorine, the most electro-negative.

The order given above corresponds fairly well with the order in the periodic table, passing from left to right. But, as in the table, the atomic weights follow each other continuously round the cylinder or round the spiral, the abrupt change from elements of an extreme electro-negative character, like fluorine to sodium, an element of highly electro-positive character, or from chlorine to potassium, has always appeared remarkable. The old dictum, *Natura nihil fit per saltum*, if not always true (else we should have no elements at all, but a gradual and continuous transition from one kind of matter to another—a condition of affairs hardly possible to realise), has generally some spice of truth in it; and it might have been predicted (and the forecast seems to have been made obscurely by several speculators) that a series of elements should exist which should exhibit no electric polarity whatever. Such elements, too, should form no compounds, and, of course, should display no valency; they should be indifferent, inactive bodies, with no chemical properties.

The discovery of argon in 1894, followed by that of terrestrial helium in 1895, and of neon, krypton and xenon in 1898, has shown the justice of the foregoing remarks. Inasmuch as the methods employed for the isolation of these elements illustrate their properties and confirm the views as to their inertness and lack of electric polarity, I propose to sketch shortly the history of their discovery.

An accurate investigation of the density of atmospheric nitrogen and of nitrogen prepared from its compounds led Lord Rayleigh to inquire into the cause of the density of the nitrogen of the atmosphere exceeding that of "chemical nitrogen" by about one part in two hundred, whereas the accuracy of his experiments was such that it would have excluded an error of one part in five thousand. I need not here allude to the reasons which were at first put forward to account for this anomaly; suffice it to say that they offered no

[1] Abstract of an evening lecture delivered at the meeting of the British Association at Glasgow, September 13, by Prof. W. Ramsay, F.R.S.

explanation; and that we ultimately traced the discrepancy to the presence in "atmospheric nitrogen" of a gas nearly half as dense again as nitrogen.

A convenient form of apparatus for isolating this gas is shown in Fig. 1. The gas, air mixed with oxygen, is confined over mercury in an inverted test-tube, in contact with a few drops of a solution of caustic potash; and by connecting the rings with wires from the secondary coil of an induction apparatus, sparks pass between the platinum terminals in the interior of the test-tube. The volume of the gas rapidly diminishes; and in a few hours the gas is removed to a clean tube, and the excess of oxygen absorbed by burning phosphorus; the inert gases remain behind.

On a larger scale, the apparatus used by Lord Rayleigh, consisting of a balloon of six litres capacity, in the interior of which an electric flame is kept alight by means of a transformer, while a jet of caustic alkali forms a fountain in the interior, gives good results. By its help seven or eight litres of mixed gases can be made to combine per hour.

Such experiments show the inactive nature of the argon group of gases towards an electro-negative element, oxygen.

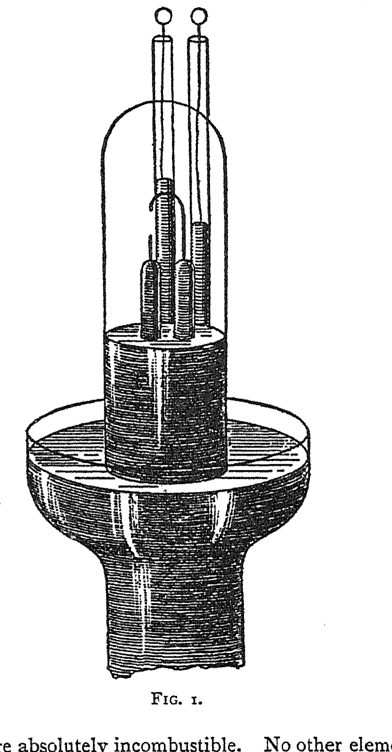

FIG. 1.

The gases are absolutely incombustible. No other elements can withstand such treatment, save platinum and its congeners and gold. But even these metals combine with fluorine or chlorine when heated in a current of one or other gas. Argon, however, is wholly unaffected when electric sparks are passed through its mixture with chlorine or fluorine, the two other most electro-negative elements. To them, too, it shows itself completely indifferent.

A more convenient method of separating the nitrogen from its admixture with argon in atmospheric air is by means of red-hot magnesium. The metal magnesium, which is now made on a considerable scale for photographic and signalling purposes, is a white, silvery metal, which can be planed or turned into shavings. In the early experiments a measured quantity of atmospheric nitrogen dried by passing over suitable drying agents was brought into contact with magnesium turnings, heated to redness in a tube of hard glass It has been found, however, by M. Maquenne that the metal calcium, which, for this purpose is most easily produced by heating together a mixture of magnesium filings and pure dry lime, is a more efficient absorbing agent for nitrogen, for it does not require such a high temperature and can be effected without danger of melting the glass tube. Indeed, the operation is a very easy one and can be carried out with the very simple apparatus shown in Fig. 2. M. Guntz has also found that lithium, an element belonging to the same column in the periodic table as sodium and potassium, is an exceedingly good absorbent for nitrogen, for it tarnishes in nitrogen even at atmospheric temperature owing to the formation of a nitride.

On a large scale the magnesium turnings are contained in iron tubes and the gas-holders are made of copper or of galvanised iron. By this means fifteen litres of argon were separated from about two cubic yards of air.

The inactivity of argon in contact with such highly electro-positive elements as lithium, magnesium and calcium again demonstrates its want of electric polarity. No other elements would have resisted such treatment except those of the argon group. But these are not the only data from which such a conclusion can be drawn, for it was found that no action takes place between argon and hydrogen, phosphorus, sulphur, tellurium, caustic soda, potassium nitrate, sodium peroxide, sodium persulphide, nitro-hydrochloric acid, bromine-water and many other reagents which it would be tedious to mention, all of which are remarkable for their chemical activity. We may therefore take it that the name "argon," which means "inactive," has been happily chosen.

In attempting to form compounds of argon, however, another consideration was not lost sight of; if compounds of argon were capable of existence they ought to exist in nature, and, as in all probability they would be easily decomposed by heat, it ought to be possible to decompose them with evolution of argon, which could be collected and tested. Prof. Miers, in a letter which he wrote me the day after an account of the fruitless attempts to cause argon to combine had been given to the

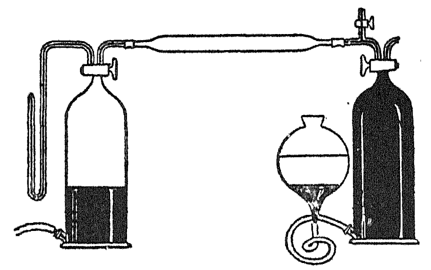

FIG. 2.

Royal Society, drew my attention to experiments by Dr. Hillebrand of the United States Geological Survey, in course of which he obtained a gas, which he believed to be nitrogen, by treating the rare mineral clevite, a substance found in felspathic rocks in the south of Norway, with sulphuric acid. The chief constituents of clevite are oxides of the rare elements uranium and thorium, and of lead. The gas obtained thus, after purification from nitrogen, was examined in a Plücker tube with the spectroscope and exhibited a number of brilliant lines, of which the most remarkable was one in the yellow part of the spectrum, similar in colour to the light given out by the glowing tube. The position of this line, and of others which accompany it, established the identity of this gas, not with argon, as was hoped, but with a supposed constituent of the sun's chromosphere, first observed by M. Janssen of Paris, during an eclipse which was visible in India in 1868. The late Sir Edward Frankland and Sir Norman Lockyer, who studied the spectrum of the chromosphere, gave to the supposititious element, which they regarded as the cause of these lines, the name "helium," a word derived from "ἥλιος," Greek for "the sun." Having been placed on the track, I examined, with the assistance of Dr. Collie and Dr. Travers, no fewer than 51 minerals, while Sir Norman Lockyer examined 46 additional ones, which we had not examined, and in 19 minerals, almost all of them containing uranium, helium was found. Only one gave an argon spectrum, namely malacone. We also sought for argon and helium in meteorites, which all give off gas on heating; but in only one specimen, a meteorite from Augusta County, Virginia, was helium found, in this case accompanied by argon. All natural waters contain argon, for that gas is somewhat soluble in water (4·1 volumes per 100 of water at 15° C.); but some also contain helium, as for instance

the gas from the Bath springs, which Lord Rayleigh found to contain argon mixed with about 8 per cent. of its volume of helium; and helium has also been found in mineral springs at Wildbad, and at Cauterets, in the Pyrenees. It would appear, then, that helium is not such a very rare constituent of our globe; and, indeed, it is probable that it is continually escaping from the earth in small quantities in certain regions.

In 1897, as president of the Chemical Section of the British Association, I chose the title "An Undiscovered Gas" for the address to the Section. The arguments in favour of the existence of such a gas were briefly these: The differences between the atomic weights of consecutive elements in the columns of the periodic table are approximately 16 to 20; thus 16·5 is the difference between the atomic weights of fluorine and chlorine; 16 between those of oxygen and sulphur, and so on. Again, stepping one pace down the scale, we have 19·5 as the difference between chlorine and manganese; 20·3 between sulphur and chromium; 19·8 between silicon and titanium, &c. The total difference between manganese and fluorine is 36; between chromium and oxygen, 36·3; between vanadium and nitrogen, 37·4; and between titanium and carbon, 36·1. This is approximately the difference between the atomic weights of helium and argon, 36. I quote now from that address: "There should, therefore, be an undiscovered element between helium and argon, with an atomic weight 16 units higher than that of helium, and 20 units lower than that of argon, namely 20. And if this unknown element, like helium and argon, should prove to consist of monatomic molecules, then its density should be half its atomic weight, 10. And pushing the analogy still further, it is to be expected that this element should be as indifferent to union with other elements as the two allied elements."

Those who care to read the story of the search for this undiscovered element may find it in the address. Minerals from all parts of the globe, mineral waters from Britain, France and Iceland, meteorites from interstellar space; all these were investigated without result. Helium from various minerals was separated by long and tedious processes of diffusion into a possibly lighter portion, diffusing more rapidly, and a possibly heavier portion diffusing more slowly, but with no positive result. The systematic diffusion of argon, however, gave a faint indication of where to seek for the missing element, for the density of the more rapidly diffusing portion was 19·93, while that of the portion which diffused more slowly was 20·01.

The invention by Dr. Hampson of an apparatus by means of which it is possible to obtain liquid air at small expense and with little trouble placed a new instrument in our hands; and Dr. Travers and I prepared 15 litres of argon from the atmosphere, with the purpose of distilling it fractionally, after liquefaction; for we knew, from the researches of Prof. Olszewski of Cracow, who has done so much to determine the properties of liquefied gases, that argon could be liquefied easily by compressing it into a vessel cooled by help of liquid air. And, moreover, we were in hope that by fractionating the air itself gases of even higher atomic weight than argon might possibly be obtained. Both expectations were realised; on distilling liquid argon the first portions of gas to boil off were found to be lighter than argon, and on allowing liquid air to boil slowly away heavier gases came off at the last. It was easy to recognise these gases by help of the spectroscope, for the light gas, to which we gave the name *neon*, or "the new one," when electrically excited emits a brilliant flame-coloured light; and one of the heavy gases, which we called *krypton*, or "the hidden one," is characterised by two brilliant lines, one in the yellow and one in the green part of the spectrum. The third gas, named *xenon*, or "the stranger," gives out a greenish-blue light and is remarkable for a very complex spectrum, in which blue lines are conspicuous.

Although neon was first obtained by the fractional distillation of argon, it was afterwards found convenient to prepare it direct from air. The torpedo-compressor, which is used for compressing the air before it enters Dr. Hampson's liquefier, was made to take in the air which had escaped liquefaction in the liquefier; the denser portions were thus liquefied, and the lighter portions were liquefied by compressing them into a vessel cooled by the denser fractions, boiling under reduced pressure, and consequently at a specially low temperature. This liquefied portion was again fractionated, and yielded neon; and it was not long before we discovered that helium was also present in the mixture. The presence of helium in atmospheric air had previously been noted by Prof. Kayser of Bonn, and by Prof. Friedländer of Berlin, on submitting the spectrum of argon to a searching examination.

The purification of this mixture of neon and helium from argon, although a lengthy process, was not attended by any special difficulty. It was accomplished by repeated distillation, the lighter portions being always collected separately from the heavier portions, and again distilled by themselves. But after this separation had been accomplished, we found that we were unable by means of liquid air to liquefy the mixture, or indeed any portion of it. We effected a partial separation by diffusion; but it is not possible to separate by this method two gases of which the quantity is limited. Another attempt was made by dissolving the gases in liquid oxygen, on the supposition that neon might prove more soluble than helium; but without satisfactory results. It was evident that a lower temperature than that possible by help of liquid air was necessary.

Prof. Dewar had by that time succeeded in producing liquid hydrogen in quantity, and had indicated the principle, which is identical with that of Dr. Hampson's air-liquefier, although he has not published any detailed account of his apparatus. Dr. Travers undertook to investigate the subject; and after four unsuccessful trials he made a liquefier, with the help of Mr. Holding, the laboratory mechanician, by means of which a hundred cubic centimetres of liquid hydrogen could be easily and cheaply produced. There was then no difficulty in effecting the separation of neon from helium; for, while neon is practically non-volatile, when cooled by liquid hydrogen, remaining in the state of solid or liquid, even that enormously low temperature is not sufficient to convert helium into a liquid. Hence the gaseous helium could be pumped away from the non-gaseous neon, and the latter was obtained in a pure state.

The residues obtained from the evaporation of about thirty litres of liquid air, after being freed from oxygen and nitrogen, were liquefied by help of liquid air, and fractionated from each other. The separation offered no special difficulty, but was long and tedious. It soon appeared that when most of the argon had been removed the residue solidified when cooled; but while it was possible to remove the krypton by pumping, for it goes into gas slowly even at the low temperature of liquid air, very little xenon accompanied it; for at that temperature xenon is hardly at all volatile.

Having finally separated the gases, their densities and other properties were carefully determined; and it was also proved that they are like argon and helium, inasmuch as their molecules consist of single atoms. Neon, as was expected, turned out to be the missing link between helium and argon; the atomic weight of krypton was found to be 81·6, and that of xenon 128. The volumes occupied by equal numbers of molecules of the liquefied gases were determined; and also the boiling-points and melting-points of argon, krypton and xenon. These figures are shown in the following table:—

	Helium.	Neon.	Argon.	Krypton.	Xenon.
Density of gas........	1·98	9·96	19·96	40·78	64·0
Atomic weight.........	3·96	19·92	39·92	81·56	128·0
Density of liquid ...	0·3 (?)	1·0 (?)	1·212	2·155	3·52
Boiling-points.........	—	—	−186·1°C.	−151·7°C.	−109·1°C.
Melting-points	—	—	−187·9°C.	−169·°C.	−140·°C.
Critical temperatures	—	—	−117·4°C.	− 62·5°C.	+ 14·75°C.
Critical pressures ...	—	— (Metres.)	40·20	41·24	43·50
Refractivity of gas...	0·124	0·235	0·968	1·450	2·368

In every case there is seen what is termed periodicity; that is, a gradual alteration with rise of atomic weight, of the densities of the liquids, of the melting-points, of the boiling-points, and of the retardation of light when passed through the gas.

Let us consider, in conclusion, the position of these elements in the periodic table; and it will be sufficient to confine our attention to he groups of elements which form the neighbouring columns. The atomic weights are given in round numbers.

Hydrogen.	Helium.	Lithium.	Beryllium.
1	4	7	9
Fluorine.	Neon.	Sodium.	Magnesium.
19	20	23	24
Chlorine.	Argon.	Potassium.	Calcium.
35·5	40	39	40
Bromine.	Krypton.	Rubidium.	Strontium.
80	82	85	87
Iodine.	Xenon.	Cæsium.	Barium.
127	128	133	137

It is evident that these new elements fall into their natural places between the strongly electro-negative elements of the fluorine group, and the very electro-positive elements of the

lithium group, and that, in consequence of their lack of electric polarity and their inactivity they form, in a certain sense, a connecting-link between the two. It is curious, too, to notice that iodine, xenon, cæsium and barium form the ends of their respective columns. It is, of course, not impossible that other elements may be discovered, possessing similar properties, and yet higher atomic weights than these; but as yet there is no clue to guide us where to search for them.

It is difficult, owing to the impossibility of effecting a complete separation of the inactive elements from each other, to do more than hazard a guess as to their relative amount in air. As they are easily separated from the other constituents of air, there is no doubt as to their total amount; air contains 0·937 parts of argon and its companions by volume in 100 parts. Perhaps the table below may be taken as affording some indication of their relative amounts. Air contains by volume:—

0·937 part of argon per hundred.
One or two parts of neon per hundred thousand.
One or two parts of helium per million.
About one part of krypton per million.
About one part of xenon per twenty million.

It is of course not impossible that xenon may contain an even smaller proportion of a still heavier gas; but it is unlikely. Sea-water sometimes contains a grain of gold per ton; that is one part in 15,180,000; a grain of xenon is contained in about four hundredweights of air.

The problems suggested by the periodic table are by no means solved by the discovery of these aërial gases; but something has been done to throw light upon one obscure corner of the field. The gap between the electro-positive and the electro-negative elements has been bridged.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

PRESIDENT ROOSEVELT has definitely decided not to accept Mr. Carnegie's offer of ten million dollars in Steel Trust bonds for public educational purposes. The provision attached to the offer to the effect that the Government should hold the bonds for a term of years is regarded as being especially objectionable.

THE scheme for the establishment of a University of Liverpool is beginning to take definite shape. A report upon the subject, submitted to the Liverpool University Committee on Monday, stated that the capital invested in land, buildings, equipments and endowments at University College, Liverpool, is not much less than 500,000*l.* To realise the ideal of a modern University, efforts will be made to raise a further capital sum of 330,000*l.* and an additional annual income of 9000*l.* Of the capital sum, 130,000*l.* would be required for additional college land and buildings. The remaining 200,000*l.* would supply an endowment for the professorial chairs and lectureships most urgently needed, especially in modern languages, chemistry and applied science, including electrotechnics. The additional yearly income of 9000*l.* would be needed for maintenance of the various departments, scholarships, equipment of the library, &c. The committee hope that the 330,000*l.* will be provided by gifts of Liverpool citizens and others interested in the highest education; and the additional income will be provided by increased grants from the Treasury, an annual grant from the Liverpool City Council, which, as it helped to create the college, will, it is hoped, give its aid in the establishment and maintenance of a Liverpool University.

THE annual conferences of science teachers arranged by the London Technical Education Board will be held on Thursday, January 9, and Friday, January 10, 1902, at the South-Western Polytechnic, Manresa Road, Chelsea, S.W. There will be four meetings, successively presided over by Mr. T. A. Organ, Sir Henry Roscoe, F.R.S., Principal Rücker, F.R.S., and the Countess of Warwick. The addresses to be delivered are as follows:—"Teaching of Hygiene," Miss Alice Ravenhill; "Mental School Hygiene," Dr. Francis Warner; "Teaching of Natural History," Mr. Frank E. Beddard, F.R.S.; "Value of Natural History Collections for Teaching Purposes," Prof. W. R. Bottomley; "American Systems of Nature Study," Mr. R. Hedger-Wallace; "Nature Study in Schools," Mr. D. Houston; "Technical Education in Rural Secondary Schools," Mr. E. E. Hennesey; "Pioneer Work in Secondary and Technical Education in Rural Districts," Prof. R. Meldola, F.R.S. A collection of home-made apparatus for science teaching in schools will be on view during the days of the conference. Applications for tickets of admission should be made to Dr. Kimmins, Park Lodge, Harrow-on-the-Hill, or to Mr. C. A. Buckmaster, 16, Heathfield Road, Mill Hill Park, W.

THE following resolutions passed by the committee of the Agricultural Education Association were confirmed at a general meeting of members held on Thursday last:—(1) That, if the Board of Agriculture retain their present educational work, it is essential that there shall be complete cooperation between that Board and the Board of Education on all educational matters specially affecting the agricultural classes. (2) That for purposes of agricultural education the country should be divided into districts, and such inspectors appointed as may be necessary. (3) That groups of counties, not yet affiliated to any collegiate centre, should be formed, each group being affiliated to some centre. (4) That, after due inquiry, reports should be issued dealing with the most appropriate forms of agricultural education for each county. (5) That permanent demonstration stations should be organised in each county or group of counties. (6) That official information bearing upon all matters of agricultural interest, whether educational or otherwise, should be distributed to the public free of cost. (7) That to carry out the above objects it is essential that larger funds be placed at the disposal of the Board of Agriculture for educational purposes. (8) That the work of the Board of Agriculture might be facilitated by the appointment of a consultative committee on the analogy of those of the Board of Education and of the Department of Agriculture in Ireland. (9) That copies of the above resolutions be sent to the Presidents of the Boards of Education and of Agriculture.

SIR WILLIAM ABNEY, K.C.B., opened the new science buildings in connection with Watford endowed schools on Thursday last. The new rooms comprise a lecture room, a physics laboratory, museum and balance room, a preparation room and a dark room, which, with the chemical laboratory (28 ft. by 24 ft.), erected in 1892, form a serviceable set of rooms, specially designed for science teaching. The cost of the additions has been about 2000*l.*, and the sum previously expended on science buildings about 1000*l.* In the course of his remarks at the opening ceremony, Sir William Abney said he did not wish any of them to think that whilst they in the secondary branch of the Board of Education encouraged science in every possible way they discouraged the other branches of education which were given at the same time. One of the reasons for starting the schools of science on their present basis was to insure that any boy or girl going through a course of science should at the same time be educated in literary work, which was so necessary in education. Of course there was a great deal of difference between mere instruction and education. The utilitarianism of education was of minor importance; the great thing was education itself. If they could make the instruction that was given useful so much the better. In the old days the only possible means of education was by literary work, classics and so on. There was no science, and therefore they could not say that a boy or girl was to be educated in scientific methods; but he was certain those who founded schools like those at Watford were so alive to the necessity of education that they would be equally alive to the necessity of education in modern methods.

WE are glad to see that the subject of the coordination of the work of the Polytechnic Institutions of London with that of the Colleges was touched upon by Principal Rücker in the course of an address delivered at the South-Western Polytechnic, Chelsea, on Friday last. A place has been found for the Polytechnics in the reconstituted University of London, but their position is not clearly understood, and the direction in which their work may be usefully developed has not been sufficiently described. The Institutions provide opportunities for study and research, and the buildings, with those of other Colleges, help to make the University of London something more than a name. The standard of Polytechnic instruction is perhaps not so high in some cases as might be desired, but it can be raised in the course of time, and the efforts of friends of the University should be directed to this end. It is far better to make the best use of existing educational material than to neglect it. As Principal Rücker remarked, the endeavours that are being made are scattered, and the object of the University is to focus them into one strong effort in order that they may advance as a well-ordered army towards one common end. If that can be

achieved—if the Colleges and Polytechnics can be connected into one great educational machine—something worthy of the metropolis and of the Empire might be accomplished. The aims of the University of London will be, above all, practical. There should be great technical institutions which would prepare men for their work in life, and all who came within the range of the University should acquire something beyond the mere knowledge which enables them to take their parts in life.

THE connection between scientific knowledge and industrial progress was referred to by Mr. Balfour on Thursday last, in distributing the prizes and certificates to students at the Goldsmiths' Institute (see p. 136). He remarked, in the course of his address:—"I am but little qualified to speak by personal investigation or experience of the work of institutions like this; but there is one part of their labours in which I have always felt the deepest sympathy, from a strong sense of its transcendent importance—I mean the teaching which gives a sound and thorough scientific training to those who are engaged in any one of the many pursuits which have a genuine scientific knowledge at their base. I am quite sure that, if we were to gauge the deficiencies of British education as compared, let us say, with German education, they would be found more striking in this branch of education than almost in any other. I am strongly convinced that not only is the necessity of a thorough scientific training great at the present moment, but that the necessity is one which grows with every new discovery. There was a time when in reality theoretical scientific knowledge was wholly divorced from manufactures or any form of practical industry. That state of things has long passed away; and now the alliance between the most abstruse scientific investigations and the general manufacturing output of the country is becoming closer and closer. What was yesterday the curiosity of the laboratory will to-morrow be manufactured in the gross and exported from this country, or from other countries, to every quarter of the globe. And no mere surface knowledge, no mere acquaintance with the methods in fashion at a particular moment, can possibly replace that knowledge of principle which lies at the very root of all these discoveries, and which must be possessed by those who are to attain the greatest success, either as the guides and leaders of manufacturing industry or as the inventors who are to increase the sum of human happiness and health by the work of their brains." The Lord Chief Justice gave expression to similar views in an address delivered at the Rutlish Science School, Merton, on Monday. He remarked that there was not the smallest doubt that what was required in these days—not only in Great Britain, but throughout the British dominions—was a more accurate scientific teaching, a more practical scientific teaching. We were, at the present time, suffering from the fact that those in charge, not only of our commercial supremacy, but of our education, up to some ten or fifteen years ago, had not realised that other countries had discovered that the root of all successful commercial enterprise must be scientific knowledge and investigation.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 21.—"Observations on the Physiology of the Cerebral Cortex of some of the Higher Apes." (Preliminary communication.) By A. S. F. Grünbaum, M.A., M.D. Cantab., M.R.C.P., and Prof. C. S. Sherrington, M.A., M.D., F.R.S.

Our experiments have been carried out on individuals representing the four species *Pithecus satyrus* (Orang), *Troglodytes gorilla* (Gorilla), *Troglodytes niger* (Chimpanzee), and *Troglodytes calvus* (Chimpanzee). The specimens so far have included ten adult individuals.

I. *Method employed.*

The method of excitation employed for the cortex has been unipolar faradisation, in the manner previously adopted by one of us (Sherrington, Roy. Soc. *Proc.*, vol. lii., 1893) in examining the cortex cerebri for ocular reactions. This method allows of finer localisation than that possible with the double-point electrodes ordinarily used.

II. "*Motor*" (*so-called*) *Area.*

This area we find to include continuously the whole length of the precentral convolution. It also enters into the whole length of the *sulcus centralis*, with the usual exception of its extreme lower tip and its extreme upper tip.

In all the animals examined, we have found the "motor" area not to at any point extend behind *sulcus centralis.*

On the mesial surface of the hemisphere the "motor" area has extended less far down than was expected. It has not extended to the calloso-marginal fissure. Certain areas near that fissure have yielded us movements, *e.g.* of shoulder, body, wrist and fingers; but we hesitate, for reasons to be given in a fuller communication, to class those with those of the "motor" area proper.

We have found the precentral convolution excitable over its free width, and continuously round, into and to the bottom of the *sulcus centralis.* The "motor" area extends also into the depth of other fissures besides the Rolandic, as can be described in a fuller communication than the present. The hidden part of the excitable area probably equals, perhaps exceeds in extent, that contributing to the free surface of the hemisphere. We have in some individuals found the deeper part of the posterior wall of the *sulcus centralis* to contribute to the "motor" area.

In the "motor" area we have found localised, besides very numerous other actions, certain movements of the ear, nostril, palate, movements of sucking, of mastication, of the vocal cords, of the chest wall, of the abdominal wall, of the pelvic floor, of the anal orifice and of the vaginal orifice.

We find the arrangement of the representation of various regions of the musculature follow the segmental sequence of the

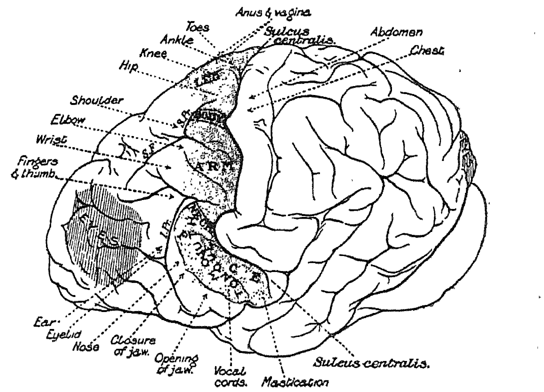

FIG. 1.—Brain of a Chimpanzee (*Troglodytes niger*). The extent of the "motor" area on the free surface of the hemisphere is indicated by the black stippling, which extends back to the *sulcus centralis.* There exists much overlapping of the areas and of their subdivisions which the diagram does not attempt to indicate. S.F. = superior frontal sulcus. S.Pr. = superior precentral sulcus. I.Pr. = inferior precentral sulcus.

cranio-spinal nerve-series to a very remarkable extent. The accompanying figure indicates better than can a verbal description the degree of adherence to this sequence.

We do not find that for the anthropoid brain the exciting current for the "motor" cortex requires to be extremely strong. "Epilepsy" is easily evoked from the cortex of the anthropoids.

Our experiments show that the *sulci* in the region of cortex dealt with can in no sense be considered to signify physiological boundaries. Further, the variation of the *sulci* in these higher brains is so great from individual to individual that, as our observations show, they prove but precarious, even fallacious, landmarks to the details of the true topography of the cortex.

Extirpation of the hand area by itself has been followed by severe paresis of the hand, the hand being for a few days practically useless and seemingly "powerless." In a few weeks use and "power" were remarkably regained in the hand, so that it was once more used for climbing, &c. The animal ultimately not unfrequently fed itself with fruit, making use of that hand alone. Even small ablations in the precentral gyrus have led to severe though quickly diminishing pareses. On the other hand, ablations of even large portions of postcentral gyrus have not given any even transient paresis.

III. *Other Regions of Cortex.*

Our observations indicate that the frontal region, yielding conjugate deviation of the eyeballs, presents such marked

differences of reaction from the "motor" area of the Rolandic region that we hesitate to include it with the so-called "motor" cortex. Spatially it is wholly separate from the Rolandic "motor" area by a field of "inexcitable" cortex. As to the occipital lobe, only from the extreme posterior apex of the lobe and from its actual calcarine region has faradisation yielded any movement (eyes), and then not easily.

The spinal degeneration resulting from ablation in the precentral gyrus of the above-mentioned "hand" area, discovers in the anthropoid cord the human feature of a perfectly large direct ventral (Türcksbündel) as well as crossed pyramidal tract. The relative sizes of these tracts seem about the same as in man.

"The New Biological Test for Blood in Relation to Zoological Classification," by George H. F. Nuttall, M.A., M.D., Ph.D. (Cambridge).

Attention is directed to experiments which prove the value of the biological test for blood in relation to zoological classification. The test is made by means of antisera, which are produced by injections of blood into various animals. If human blood, for example, is injected intraperitoneally into rabbits, the serum of the latter animals, after a course of such treatment, acquires the property of producing a precipitation when it is added to dilutions of human blood. By means of such anti-serum a positive reaction may be obtained with solutions of dried human blood. The anti-serum for human blood also acts on the blood of monkeys. The bloods of eighteen species of monkeys, representing the four families Hapalidæ, Cebidæ, Cercopithecidæ and Simiidæ, all reacted to human anti-serum. The bloods of the first two families (New World apes) gave less reaction than those of the two latter families (Old World apes). Upwards of 200 bloods from other animals gave no such reaction with human anti-serum. In other words, the test has established the existence of a *blood relationship*, as Dr. Nuttall terms it, between the apes and man. It will be remembered that Darwin considered the Old World apes to be more closely related to the Hominidæ than the New World apes, and the degree of reaction obtained with the latter bloods certainly supports this view. Among the bloods which gave no reaction with human anti-serum were those of two species of Lemur.

Similarly, dog anti-serum only produced a reaction in the blood of four other species of Canidæ. The anti-serum for ox and sheep blood only produced reactions in the bloods of other true ruminants (negative with Tragulus and Camelus), the anti-serum for horse blood only reacted wlth the blood of the horse and donkey, &c. These investigations are being prosecuted upon an extended scale.

Hitherto purely morphological characters have served for purposes of classification in the animal kingdom. We now possess a test whereby chemical differences may be determined between the bloods of different animals, as also, to a certain extent, between the bloods of related species, the differences in the latter case being quantitative. Dr. Nuttall believes that it will be possible by means of this test to determine certain relationships which have hitherto been considered obscure. It is certainly a remarkable fact that a fundamental chemical character has persisted in the bloods of all the Anthropoidea, in spite of the widely divergent modes of life and the different character of the food. Limited space prevents a consideration of the chemical nature of the reaction, but we might add that it is at present but imperfectly understood.

Physical Society, December 13.—Prof. S. P. Thompson, president, in the chair.—The following papers were read by the secretary:—On circular filaments or circular magnetic shells equivalent to circular coils, and on the equivalent radius of a coil, by Prof. T. R. Lyle. It is shown that we can represent the magnetic action of any coil by replacing it by one or more filamentary circuits in which currents circulate bearing a simple relation to the actual current in the coil. If the axial and radial dimensions of the coil in question are the same, then the external magnetic action can be represented by that of one filamentary circuit. If the axial breadth is greater than the radial depth we must employ two filaments of equal radii separated by an axial distance, and if the opposite condition holds, two circular filaments of different radii lying in the same plane perpendicular to the axis of figure of the coil. In the case of coils in which the axial and radial dimensions are equal, a modification of Bosscha's method is described which yields the equivalent radii directly as the result of length measurements. If the axial and radial dimensions are not equal, it is shown that the method is still applicable, provided that the ratio of the resistances of the Bosscha comparison be altered in a ratio depending on these dimensions. Apparatus for carrying out the experiment is described and applications to some classical cases are given. It is also pointed out that the correction for finite length of magnet in Bosscha's (or the present) method of comparison is in general far from negligible. The formulæ used are based on the expansion of the potential of a coil for points on its axis, and terms up to the fourth have been included, but the effect of neglecting higher terms is not investigated.—The secretary read a letter from Lord Rayleigh, in which he stated that the length of the magnet used in determining the constant of the current balance used in the determination of the electrochemical equivalent of silver was one-tenth of an inch, and the error due to neglecting this was less than one part in ten thousand.—On air-pressures used in playing brass instruments, by Dr. E. H. Barton and Mr. S. C. Laws. It is well known that in playing upon the "brass" or "wood-wind" instruments of the orchestra the particular note, at any instant desired, is produced by the simultaneous use of the mechanism of the instrument and the corresponding "embouchure" through which air at a suitable pressure is driven by the performer. The object of the paper is to find how the air-pressure required to sound the different notes varies with (1) the pitch of the note, (2) its loudness, (3) the fingering or other manipulation of the instrument, (4) on the instrument itself. Experiments were made with the tenor trombone, the trumpet and the cornet, and the pressures were taken by a water-manometer connected to the performer's mouth by an india-rubber tube terminating in a glass nozzle, which could be held by the side teeth. The following inferences are drawn from the experiments: (1) Other things being equal, the louder the note the greater the pressure. (2) The higher the pitch of the note played on a given instrument the greater the air-pressure used. (3) The curves formed by plotting the logarithms of the frequencies of the notes as abscissæ and the pressures as ordinates are straight lines. (4) The air-pressure required to sound any note with given intensity is approximately proportional to its pitch defined logarithmically. (5) Where alternative positions or fingerings are used for the same note the pressures are practically the same. (6) The pressures for identical notes on trumpet and cornet are almost the same for any given intensity, but very much less than those for the same notes on the trombone. (7) The pressures used for loud low notes may exceed those for soft high notes.—On a new hygrometric method, by Mr. E. B. H. Wade. In this method a thermometer is wetted, not with water, but with sulphuric acid of such a strength that the temperature of the acid bulb is close to that of the dry bulb. The maximum tension of the acid at any temperature is known from Regnault's work, and two or more determinations with this instrument and with a wet and dry bulb hygrometer at the same time enable the constants of both instruments to be determined. If the difference between the acid bulb and the dry bulb is less than 2°, the constant remains fixed over a large range. Experiments show that the readings of the instrument are not affected by ventilation, and since the difference between the temperatures of the bulbs is small, errors in the determination of the constant are unimportant.

Zoological Society, December 3.—Dr. W. T. Blanford, F.R.S., vice-president, in the chair.—Mr. W. E. de Winton exhibited a remarkably large specimen of the grey mullet (*Mugil chelo*), said to have been taken in the North Sea.—A series of papers on the collections made during the "Skeat Expedition" to the Malay Peninsula in 1899–1900 was read. Mr. F. G. Sinclair reported on the Myriapoda, and enumerated the forty species of which specimens had been obtained. Of these, nine were described as new to science. Mr. W. F. Lanchester contributed an account of a part of the Crustacea, viz. the Brachyura, Stomatopoda and Macrura, collected during the expedition, and described six new forms. Mr. F. F. Laidlaw enumerated the snakes, crocodiles and chelonians which had been obtained, and described two new species based on specimens in the collection. An appendix to these papers, drawn up by Mr. W. W. Skeat, contained a list of names of the places visited by the members of the "Skeat Expedition."—Mr. F. E. Beddard, F.R.S., read a paper on the anatomy and systematic position of the painted snipe (*Rhynchaea*), based on an examination of specimens of this bird which had lately died in the Society's menagerie. The author was of opinion that *Rhynchaea* was more nearly allied to the Parridæ than to the

Scolopacinæ. In a second paper Mr. Beddard pointed out the structural differences between the common snipe (*Gallinago coelestis*) and the jack snipe (*G. gallinula*).—A communication from Dr. R. Bowdler Sharpe contained an account of the birds collected by Dr. A. Donaldson Smith during his last expedition to Lake Rudolf and the Nile.—Mr. G. A. Boulenger, F.R.S., described two new fishes under the names *Phractura ansorgii* and *Fundulus gularis*, recently discovered by Dr. W. J. Ansorge in southern Nigeria.

Aëronautical Society, December 3.—Mr. E. P. Frost in the chair.—Papers were read by Sir Hiram Maxim on aërial navigation by bodies heavier than air, by Mr. William Marriott on atmospheric currents, and by Mr. Eric Stuart Bruce on navigable balloons and the scientific aspects of M. Santos Dumont's experiments. Sir Hiram Maxim discussed the work done in navigable balloons by MM. Giffard and Renard. Renard made return journeys, but he never tried a petroleum motor. M. Santos Dumont had done so, had driven his balloon at the greatest pace yet attained, and returned to his starting-point in face of an adverse wind. His motor and balloon had strength and lightness as great as possible, and it did not seem probable they could be improved upon, so that his results seemed carried to the line beyond which no one could go. Turning to the consideration of flying by means of bodies heavier than air, in which, as yet, only a beginning has been made, Sir H. Maxim recapitulated the details of his own machine, relating his preparatory and subsequent experiments, which latter proved that a machine on a large scale could be made to develop a lifting effect greater than its own weight. The petroleum motor would now probably yield the best results. Now, too, there were aluminium alloys strong as wrought iron and light as aluminium, and at the time that he carried out his experiments engineers had nothing so good in their hands. He considered that a flying machine was not only now possible, but practicable.—Mr. W. Marriott, in his paper on atmospheric currents, explained climate and weather as meteorological terms, mentioned the instruments used for meteorological observations, dwelt on pressure records taken on the earth, alluded to the connection between heat and pressure, and by means of a series of charts explained the direction of currents in cyclones and anticyclones. A knowledge of the velocity and direction of winds in the upper air is needed, and he called upon the Aëronautical Society to here help meteorology. Speaking of the valuable kite-observation work of Mr. L. Rotch, up to a height of 8000 feet, Mr. Marriott said that at present a free balloon drifting with the wind can obtain no record of wind pressure or wind velocity; it can only ascertain the direction of the upper currents.—Mr. Eric Stuart Bruce pointed out that for the first time in history M. Santos Dumont had succeeded in steering a balloon from a given point to a given point in a given time. His ingenuity and originality had enabled him to make a real, though small, advance in practice in overcoming the force of the wind; the observations on the Eiffel Tower showed that on the day he won the Deutsch prize the velocity of the wind during his balloon journey was from four to five metres per second. In future navigable balloon competitions, Mr. Bruce thought it should be made a condition that the trials took place when the wind-force was not below a certain value.

Linnean Society, December 5.—Dr. D. H. Scott, F.R.S., vice-president, in the chair.—Dr. W. G. Ridewood exhibited nine specimens of abnormal sacra in the edible frog (*Rana esculenta*) and one in the common frog (*Rana temporaria*).—Dr. J. H. Salter read a paper on protoplasmic connections in the lichens. The author stated, in conclusion, that the observations tended to show that a complete anatomical union exists between the several tissues of the lichen thallus, due to the innumerable connections which may be traced between the ultimate histological units, the segments of the hyphæ. Many physiological problems are simplified, and a new conception is obtained, by our ability to recognise the essential unity of the living matter throughout the organism.—Mr. F. Chapman read a paper on the foraminifera collected round the Funafuti Atoll from shallow and moderately deep water; with notes on new species from the sands of the reef slope. The descriptions were based on material collected by Profs. Sollas and Edgeworth David, and included samples from the beaches down to 200 fathoms and also from the reef slope. They serve as an index to the forms found in the reef-boring. Some idea of the richness of the dredgings may be gathered from the fact that no less than 273 distinct forms are recorded from the dredgings taken between 16 and 200 fathoms. From these samples fourteen new species and varieties have been described.

PARIS.

Academy of Sciences, December 9.—M. Fouqué in the chair.—On the connection of algebraic surfaces, by M. H. Poincaré.—Studies on radium, by M. Berthelot. A detailed study of the action of radium salts upon iodic anhydride. The experiments were carried out at two temperatures, 10° and 100°; blank experiments were carried out, always in the dark, in such a manner as to distinguish between the effects of the phosphorescence produced by the radium and the effects produced by the radium rays in the absence of this phosphorescence. In the case of the iodic acid submitted to the action of the radium tube wrapped round with black paper, that is, protected from the phosphorescence, no reduction took place, whilst in the tube not thus protected iodine was formed. The amounts produced were of the same order of magnitude as the effects observed previously by M. Curie and M. Becquerel.—On the radio-activity of uranium, by M. Henri Becquerel. The observations published by Crookes and by Giesel would tend to show that the activity of uranium may be due to the presence of a small quantity of a very active compound, and that uranium itself is really inactive. This, however, is hardly consistent with the fact that the radio-activity of a commercial uranium salt, whatever may have been its origin, is practically constant. In some earlier work, some uranium salt was fractionated and the radio-active effects concentrated in certain fractions; after the lapse of about eighteen months these fractions were re-examined and were found to have practically the same activity. The lost activity is thus regained spontaneously. A hypothesis is developed which is in accord with most of the observed facts.—The production and maintenance of low temperatures, by M. d'Arsonval. For temperatures down to about −110° the use of solid carbonic acid or acetylene in acetone is recommended, and the necessary precautions given for the maintenance of a steady temperature. For lower temperatures liquid air must be used; it has been found possible to use a bath of carefully rectified petroleum spirit, which remains liquid even at −194°.—Remarks by M. Dehérain on his treatise on agricultural chemistry.—On persistent conjugated systems, by M. A. Demoulin.—On transcendental equations and numbers, by M. Edmond Maillet.—The determination of the observed heights of shooting stars in August, 1901, between the Observatory of Juvisy and the auxiliary station of Antony (Croix-de-Berny), by M. C. Flammarion. The results of the measurements of eight meteors are given, the heights of the first appearance varying between 119 and 15 kilometres, and the heights of the disappearance varying between 68 and 14 kilometres.—A method allowing of the determination of the true velocity of navigable aërostats, by M. H. Deslandres.—A note completing that of November 25 and giving the trace of the trajectory on the ground, with an approximation of about 1/25, of the course of M. Santos Dumont's aërostat on the trial of October 19, by M. J. Armengaud, jun.—The influence of stray currents upon the terrestrial magnetic field, by M. Th. Moureaux. It has been found that in spite of the employment of deadening apparatus the establishment of electric tramways affects, not only the diurnal variation, but also the absolute magnetic elements.—On the auscultation of storms and on the study of the diurnal variation of atmospheric electricity, by M. Th. Tommasina.—On the alloys of aluminium and magnesium, by M. O. Boudouard. The compound Al_4Mg was isolated, and its properties are given. Particulars are also given of the preparation and properties of $AlMg_3$ and AlMg.—On the alloys of strontium with zinc and cadmium, by M. Henri Gautier.—On the state of silicon in cast iron and in ferrosilicons containing a small amount of silicon, by M. P. Lebeau. The compound SiFe cannot exist in the presence of an excess of iron and consequently cannot form a constituent of siliceous cast irons. All the silicon in cast iron would appear to be in the state of the silicide $SiFe_2$.—On a practical means of obtaining trichlorbutyl alcohol, by M. Marcel Guédras. Trichlorbutyl alcohol is prepared by the action of caustic potash upon a mixture of acetone with chloroform. This alcohol is a local anæsthetic, and also possesses antiseptic properties.—On the nutrition of the embryo at the expense of the cotyledons, by M. G. André.—The structure of the lymphatic ganglions of the goose, by MM. L. Vialleton and G. Fleury.—The inoculation of cancer from man to the white rat, by M. Mayet.

—On the existence in cold-blooded animals of a regulating apparatus for heat, by M. J. P. Langlois. Reptiles with impermeable skin have the power of regulating their temperature when it reaches 39° and when the calorific rays strike the head directly.—On the salutary effects of potatoes substituted for bread in diabetics in high doses sufficient to maintain the equivalence of the food ration, by M. A. Mossé. The carbohydrates which may be given to diabetics can be divided into three classes—harmful, indifferent and doubtful—and the potato has been generally placed in this last group. From the experiments here described, the author concludes that the potato is not only permissible, but useful, and may be advantageously substituted for bread.—Organic variations in the hen with respect to its food, by M. F. Houssay.—On the transformations of the germinative vesicle in lizards, by Mlle. Marie Loyez.—Properties of the liberoligneous chains in ferns, by MM. C. E. Bertrand and F. Cornaille.—A contribution to the study of a new disease of the potato produced by the *Bacillus solancola*, by M. G. Delacroix.—The influence of nutritive mineral salts on the production of nodosities in peas, by M. E. Marchal.—Conclusions to be drawn from the study of the series of homogeneous enclosures in a volcanic rock; the series of homogeneous enclosures in the andesites from Mont-Dore, by M. A. Lacroix.—The gases of the blood at different altitudes during a balloon ascent, by MM. J. Tissot and Hallion. The decrease of atmospheric pressure caused by a balloon ascent causes a sensible increase in the power of absorbing oxygen possessed by the hæmoglobin; up to 3500 metres the carbonic acid contained in the blood does not follow the law of solution of gases, on the contrary it varies in the inverse sense. The nitrogen in the blood follows the ordinary laws, the amount diminishing as the pressure is reduced.—Reproductions of the Palæolithic drawings engraved on the walls of the cave of Combarelles, by MM. Capitan and Breuil. The paper is accompanied with reproductions of drawings of a horse, reindeer, mammoth and bison.

NEW SOUTH WALES.

Linnean Society, October 30.—Mr. J. H. Maiden, president, in the chair.—On *Eucalyptus pulverulenta*, Sims, by Mr. J. H. Maiden. The author shows that *E. pulverulenta*, Sims, is conspecific with the "apple or peppermint" of Victoria (one of the trees known as *E. Stuartiana*, F.v.M.) and the "red or black peppermint" of New England (*E. nova-anglica*, Deane and Maiden), both of which he considers to be lanceolar-leaved forms of the species.—On *Eucalyptus Stuartiana*, F.v.M., by J. H. Maiden. The author shows that at least three species of trees have passed under this name, and expresses regret that it is not possible to obliterate the name from the list of species. As this is out of the question, he reiterates the former recommendation of Mr. Deane and himself that its use be confined to the "apple or but but" of Victoria and to the "apple or white peppermint" of New South Wales, the species that probably extends over a greater area than that of any of the other plants included under the name, and the one which was perhaps most frequently named *E. Stuartiana* by Mueller himself.—On *Eucalyptus Gunnii*, Hook. f., by Mr. J. H. Maiden. The author divides the species into the type-form and four varieties, viz., vars. *acervula*, *ovata*, *rubida* and *maculosa*.—The gum-fermentation of sugar-cane juice, by Mr. R. Greig Smith. The viscosity that occasionally develops in cane juice during the manufacture of sugar has been traced to *Bacillus levaniformans*, n. sp., which ferments saccharose producing gum, a mixture of reducing sugars, carbon dioxide and a mixture of acids. Neither mannite nor alcohol is formed. In a culture medium containing 100 grms. saccharose, 1 grm. peptone and salts dissolved in a litre of water, 31 grms. gum and 60 grms. mixed reducing sugars were produced in seven days at 37° C. The gum is formed from saccharose, but not from lactose, dextrose, levulose, maltose, starch or vegetable infusions without saccharose. Peptone increases the gum and acids relatively, and decreases the mixed reducing sugars. The fermentation goes on, though slowly, in weak peptone (·001 per cent.) solutions. The chemical and optical properties of the gum, which is probably the diffluent capsule of the bacillus, show it to be different from inulin, levulan and other previously described gums; it has, therefore, been named levan. Carbon dioxide is produced in good amount, 1·28 grms. being formed from 100 grms. saccharose in five days. The acids are comparatively small in amount, and consist of active and inactive lactic, butyric, acetic, formic and capric acids. These occur in the ratio of about 60 of lactic acid to 1 of the rest. Many races of *Bac. levaniformans* were separated from other sources, and these showed that the organism is related to the potato group of bacilli as a whole and not to any one so-called species.—The chemical properties of bacterial gum levan, by Mr. Thos. Steel. The chemical properties of levan, the new gum produced by the action on sugar of the bacillus described by Mr. R. Greig Smith in the preceding paper, are described. The relationship of levan to other similar known substances is detailed, and it is shown to differ in important respects from inulin, the body which it most nearly resembles generally. The gum found in sugar-cane suffering from the well-known "gumming" disease is quite distinct from levan.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 19.

LINNEAN SOCIETY, at 8.—On the Brain of Recent and Fossil Lemurs: Dr. G. Elliot Smith.—On the Ostracoda collected round the Funafuti: F. Chapman.—Exhibitions: A Gigantic Argulus from Japan and a Specimen dredged at the Cape: Prof. G. B. Howes, F.R.S.—A New Polyzoon from Tanganyika: J. E. S. Moore.—An Example of White's Thrush (*Turdus varius*), shot near Clavering, Essex: Miller Christy.

FIRE PREVENTION.

Publications of the British Fire Prevention Committee, Vols. i to iii., 1898 to 1900. (1, Waterloo Place, S.W.)

THE subject of Fire Prevention is somewhat curiously manifold. The best mode of securing permanent peace is to prepare continually for war, and the most likely way to prevent fire is to have every means of combating it in perfect readiness, so that at the earliest symptom of danger immediate steps can be taken to reduce the temperature. To secure this end knowledge is necessary, and where there is real knowledge there is not much difficulty.

Buildings should be constructed of such materials and in such forms as experience has proved to be necessary for the safety of the contents, whether merchandise or persons, and at the same time the cost must be kept within such reasonable limits that the responsible public or private authority may be justified in rigorously enforcing the regulations laid down for the general good.

To construct a building, as is generally the case, without any regard to its safety from fire, and after its completion to call in an expert to arrange for its protection, is a most expensive and unsatisfactory proceeding.

All the arrangements for its protection should be shown on the original working drawings before a single brick is laid, or even the foundation prepared; and, where this is done with knowledge, no expense whatever, or, at worst, a minimum of expense, will be incurred.

For the protection of merchandise a building can be so divided by fire-proof partitions that the contents of any compartment in it may be burnt out without affecting any other compartment, even when no external aid for extinguishing a fire is available, and this is all that can be done in the way of construction; but there is no difficulty in doing it.

For the protection of life a building should be so arranged that there shall be clear and simple modes of immediate exit within the time necessary for safety in accordance with the nature of the contents.

For instance, in a carpenter's workshop in which no artificial heat is used, and the light is supplied by electricity, a large number of persons can have plenty of time to pass out by ordinary doors in case of emergency, and the same may be said of a warehouse not containing inflammable stock; but it is a very different matter where volatile oils or explosives are stored and manipulated; or where, as in a theatre, large numbers of persons are closely packed in the immediate neighbourhood of scenery or appliances likely to burst forth in flame, and produce volumes of poisonous smoke within a few minutes. It is much more difficult to protect life than property; but it is by no means impossible within reasonable limits. Both subjects may be considered separately.

Of late years much attention has been paid by architects to the materials which they use, and the result has been that new materials have been invented, and improved application of old materials adopted.

The introduction of certain metals, impossible in former years, but now easily available, was a great advance, and the protection of these metals with concrete, plaster, and other substances, has been a still further improvement, but there is something else to which attention should be called.

It may be a little invidious, and in some respects unfair, to speak disparagingly of those who have gone before us, and every allowance must freely be made for them; but to a practical student now observing buildings of one or two generations ago, it certainly does appear that in the great majority of cases there can have been no effort at adaptation.

In all our large centres of commerce and manufacture hundreds of buildings may be found which were originally quite unsuitable to the purposes for which they were used; and, even after expensive alteration and dangerous patching, are by no means either economical or convenient for profitable working at present.

Latterly, however, architects seem to have studied the business of their clients, and on every side we see evidence of thoughtful, practical adaptation for the requirements of every kind of service—private houses, offices, warehouses for all the numerous descriptions of stock, factories for all the various methods of mechanical engineering, placing the fires, the forges, the lathes, the stores and everything else that is necessary in the relative position most suitable for speedy and economical work, and churches and other buildings in which large numbers of persons are assembled. There is still room for improvement in theatres; but there are signs that this is coming or will come in time.

The great hotels and clubs of the present day compared with those of past generations, or even those of twenty years ago, are as palaces to pig-sties, and this improvement is entirely the work of architects who have studied the requirements of their employers.

In the year 1882 the Secretary of State for the Home Department (it is supposed at the special desire of her late Majesty, Queen Victoria) requested from the Metropolitan Board of Works, "A report from the Fire Brigade as to the actual condition of the London theatres in respect of security from fire, stating what additional precautions they think necessary to be taken to prevent loss of life in case of conflagration;" and in the summer of that year, Captain Shaw, the chief officer of the Brigade, made a detailed report on each of the forty-one theatres then existing.

This report is much too long and too full of detail for insertion here; but a few extracts from his "general remarks" at the end may be instructive.

"In dealing with the exits from theatres it is necessary to call attention to the perversity of ingenuity which characterises the arrangements of several houses for getting away. In some cases, where a whole building intervenes between the auditorium and the street, and the space actually existing is more than ample for the escape of an audience, every exertion seems to have been used to make the passages, corridors, landings and stairs as complex and tortuous as possible; and, having done this, then to obstruct them and make them still more inconvenient by pay-boxes, cloak-rooms, barriers, refreshment-counters, single or double steps and partial walls, thus causing nightly confusion and annoyance to the visitors, and adding, moreover, very considerably to their risk in case of panic from fire or any other cause."

"In many cases the first point of actual safety reached by the audience is the street door into the open air, although the removal of a few walls, barriers, pay-boxes and other obstructions, now wrongly placed, would make it 50 or 60 feet nearer the seats, and thus add greatly to the convenience and safety of the visitors."

"In some theatres the attendants seem to spend the greater portion of their time in showing visitors the way."

"I should not recommend a licensing authority to permit the existence of any exit requiring a guide, and I greatly doubt whether any should be permitted which could not be adequately described in half a-dozen words."

"For the safety of an audience it would be most important that the construction of simple separate exits should be encouraged. I should prefer to see them leading into the open air; but the point is not so much where they should lead, as that they should lead by a short route to a place of safety."

"In the event of a panic from smoke or fire or any other cause, the essential conditions of safety for an audience are light and air."

"In the event of a panic, the first steps to be taken by those responsible for the safety of an audience should be to turn on all possible lights, to drop the heat-proof curtain, and to open the smoke-outlet over the stage."

Captain Shaw gives the numbers which could be safely accommodated in the several parts of each theatre, and he makes the total number for the forty-one theatres of that date 53,326.

It is to be regretted that this report cannot be given in full; but it may be hoped that the few selected extracts will supply a general indication of its purport.

Of late years a society has been formed under the title of "The British Fire Prevention Committee," the main object of which is stated to be: "To direct attention to the urgent need for increased protection of life and property from fire by the adoption of preventive measures."

This is an admirable idea, and cannot fail to effect good practical results. The society is altogether private, and has no public authority or sanction whatever, but it is none the worse for this, and it is supported by many persons of influence and practical knowledge, including the late superindenting architect of the London County Council, and will undoubtedly be the means of calling special attention to the paramount importance of *preventive* measures, while it does not in any way ignore the absolute necessity for means of dealing promptly and effectively with catastrophes which have not been prevented.

A thoroughly efficient fire brigade can certainly do much, but, however perfect the supply and distribution of water, or the mechanical appliances and personal intrepidity and skill of the firemen may be, still the safety of any great city, and more particularly of any mercantile city containing a great amount of massed property, must eventually depend on the mode in which its buildings are constructed, and the property within them classified with special reference to risk of fire.

According to a paper read by Sir R. Giffen some years ago at the Royal Statistical Society the wealth of this country was estimated by that distinguished financial authority as 11,500,000,000*l*., or eleven thousand five hundred millions sterling, and Sir John Lubbock, about the same time, stated that a sum of nearly eight thousand millions was passed into the London Clearing House in one year.

Both these amounts would now be considerably increased; indeed, a recent number of the *Saturday Review* gives the annual amount now passing through the London Clearing House at more than eleven thousand millions sterling; but how closely these figures represent the actual value of property liable to be consumed by fire it is difficult to say.

A consideration, however, of the deliberate statements made by such high authorities as these must show beyond doubt that this country contains an amount of material wealth unparalleled in history, and common sense indicates that it is a national duty to preserve it as far as possible from diminution or annihilation.

EMERITUS.

CUNEIFORM DECIPHERMENT.

Assyrian Language. Easy Lessons in the Cuneiform Inscriptions. By L. W. King. Pp. xv + 216. (London: Kegan Paul and Co., Ltd., 1901.) Price 3*s*. 6*d*. net.

MR. KING'S modest little volume on the Assyrian language will, we believe, be welcomed by many who are not Assyriologists, because it contains a brief but lucid exposition of the principles upon which the decipherment of Assyrian is based. It is now many years ago since the first labourers in the stubborn field of Assyriology produced their first fruits, and as two generations of men have grown up since that time the early labours of Rawlinson, Lassen, Hincks, and Norris have become well nigh forgotten. Mr. King's book is, as its title signifies, intended to help beginners in the study of Assyrian to master that difficult language, but it is good to note that he also means the beginner to come behind the scenes and to see, not only the results, but how the results have been arrived at. In these days we are so much accustomed to see translations of cuneiform documents in English, French and German that it is hard to realise that less than fifty years ago the phonetic values of a great number of Assyrian characters were unknown.

The first chapter deals with cuneiform writing, and shows how it came into being and developed. Though so different in appearance now, the cuneiform characters were originally of a pictorial origin, and they appear to have been invented by the Sumerians, a race of people who are generally believed to have come from a Turanian stock. Their earliest forms we now know did not consist of wedges, but of *lines*, and in the characters of *linear* Babylonian the natural objects which they were intended to represent can still be traced. In a table on p. 4 Mr. King gives us four distinct forms of fourteen characters, which date from B.C. 4500, B.C. 2500, B.C. 700, and B.C. 500 respectively; these illustrate clearly the manner in which linear picture forms become groups of wedges, and in a series of notes he shows by comparisons with Egyptian hieroglyphics that the old Sumerian characters, when they were first written down, must have been very similar to those of ancient Egyptian. The Assyrians appear to have been ignorant of this fact, and it is quite clear from their lists of archaic

characters that they could do little more than speculate about it. Mr. King decides, and rightly, that the cuneiform system of writing was produced by the material upon which the Sumerians and Babylonians wrote. On stone it was comparatively easy to cut linear characters, or even signs in which circles and semicircles occurred; but on clay a circle or a crescent could not be made quickly with the three or four-sided stylus, and the outline of a round, or oval, object had to be represented by a series of wedges. That clay became a popular material for writing upon is proved by the fact that its use extended from Elam in the east to Syria in the west, and from Lake Van in the north to the head of the Persian Gulf in the south; the cuneiform system of writing was in use continuously in Mesopotamia for about 4500 years.

Passing next to the decipherment, in an interesting chapter there is set before us the history of the discovery of the Persepolitan inscriptions by early travellers, such as Antonio de Gouvea and Garcia de Sylva y Figueroa, Pietro della Valle and others; the first useful copy of these was made in 1765 at Persepolis by the great Niebuhr. The first successful step towards decipherment was made by Grotefend, but it was not until 1837, when the late Sir Henry Rawlinson took the matter up, that any substantial results were obtained. Mr. King gives us copies of the inscriptions from which Sir Henry recovered the names of Darius, Hystaspes, and Xerxes, and clearly explains his method step by step, and two "cuts" give us an idea of the situation of these important inscriptions on the rock at Elwend and of the famous trilingual inscription at Behistun. The narrative of the manner in which Sir Henry overcame all difficulties is extremely interesting, and the world owes almost as much to his physical as to his mental energy.

Want of space prevents us from doing more than mention the Susian and Babylonian texts at Behistun, and we therefore pass on to note that the third chapter is devoted to a description of the system in which cuneiform characters are employed as syllables, ideographs, and determinatives. It is astonishing that the Assyrians or Babylonians did not reduce their cumbrous syllabary to an alphabet, as did the Egyptians and the Persians. Following this description we have a good selection from the Assyrian syllabary, printed in the cuneiform character, with syllabic and ideographic values, &c. The latter part of Mr. King's work contains a series of interesting extracts from cuneiform texts, with transliteration and translation arranged with them either interlinearly or on the opposite page, and the last few pages of the volume are devoted to a small glossary. For a book of the size no one could expect long dissertations on abstruse points of grammar or history, it being clearly understood that for matters of this kind the advanced student must consult the larger works on Assyriology.

The little volume before us is admirably suited for the purpose for which it is intended, viz., to enable the beginner to lay hold upon the first principles of the Assyrian language, and the frequent use of cuneiform type throughout its pages will help him to become familiar with the difficult character in which the sages of Mesopotamia in all ages seem to have written down their wisdom. The cuneiform type is clear and very legible, and is, if we mistake not, copied from the fount which was specially cast for Rawlinson's "Cuneiform Inscriptions," but was at the last moment abandoned in favour of lithographic copies of texts made first by Mr. Bowler and after his death by Mr. Jankowski.

ELEMENTARY HISTOLOGY AT CAMBRIDGE.

Practical Histology. By J. N. Langley, M.A., Sc.D., F.R.S. Pp. viii + 340. (London: Macmillan and Co., Ltd., 1901.) Price 6*s.*

THIS book is an embodiment of directions for practical work in animal histology, which the author, as the result of twenty years' experience, has been led to regard as best suited to the requirements of the elementary student, with the greater part of those of the histological section of the last edition of the "Practical Physiology and Histology," by Sir M. Foster and himself—one of the best established of the famous red-cover series of didactic manuals for students, which have done so much for the practical side of modern scientific instruction. The body of the book (286 pp.) is divided into thirty-six lessons, of which the first eight are devoted to methods and the use of the microscope and microtome. Those numbering nine to thirty-five are set aside for the tissues and organs, and the thirty-sixth deals very slenderly with the main facts of cell-division. In each of these "lessons" there are first given such accounts of the organs and tissues as are necessary for manipulative purposes, and descriptions of methods of treatment likely to yield constant results in the student's hands. There follows for each lesson, under the heading "Demonstrations," a list of objects to be correlatively studied or examined; and finally (in small type) a series of "Notes," having reference to cognate and alternative objects of interest and to methods supplementary to those described in the body of the lesson, with especial reference to such as require particular skill and attention or are variable and uncertain in their action. *Apropos* of this arrangement (which is but an extension of that adopted for the volumes which preceded the present one) and the "Notes," the author points out, with commendable care, that he has been careful to avoid making manipulation too much of an end in itself; and he thereby introduces a welcome check to the tendency on the part of pure histology to lapse into a mere laborious idleness.

The book is up to date and evenly balanced, and is sure of success equal to that of its predecessors. In his acknowledgments to those who have helped him the author naïvely alludes to the "unending suggestions" for "modifications in procedure," and we have these in evidence in many of the pages of the book.

It may now more than ever be said of animal histology that the history of its progress is that of method, since, on this basis, the far-reaching generalisations of Ramon y Cajal, which but seven years ago threatened to revolutionise our conceptions of the structure and mode of action of the nervous and sensory epitheloid apparatus, are by Apathy and others being challenged. Cajal's methods receive recognition in the present work. While we could hardly expect this for Apathy's until more fully confirmed, we could desire a fuller recognition of the discovery by Dogiel of the double innervation of

Meissner's corpuscle, and of the rapidly accumulated evidence of the same condition in that of the Pacinian, Herbstian, and even the Grandryian type. This discovery, which we owe to Dogiel and his pupils, with Timofeew and Sala, imparts a new character to the tactile body in all its forms; and it marks one of the most welcome and important advances in recent histological work, demanding the attention of even the elementary student. If only it had been made in Cambridge!

OUR BOOK SHELF.

A Catalogue of the Lepidoptera of Ireland. By W. F. De Vismes Kane. With a coloured plate. Pp. xviii + 166. (London: West, Newman and Co., 1901.) Price 10*s*.

THE earliest catalogues of Irish Lepidoptera were published by the Rev. Joseph Greene and the Rev. A. R. Hogan in 1854 and 1855 in the first two volumes of the *Natural History Review*, but were merely tentative, not only being very incomplete, but including many species on the evidence of collections without history, or else taken in localities where they were almost certainly introduced. These authors enumerated 636 species as Irish. The late Edwin Birchall's list, published in the *Entomologists' Monthly Magazine* from 1866 to 1868, was a much more valuable work. Mr. Birchall enumerated 974 species, though several included in the former lists were very properly omitted. The list now before us, which was originally published in the *Entomologist* from 1893 to 1900, is carefully compiled, chiefly from original sources, and brings down the subject to the present time; but the species are not numbered, and no comparison is made, as should have been done, with the number given in Mr. Birchall's catalogue.

Mr. De Vismes Kane's book will be very useful to entomologists visiting Ireland, or to those anxious to study the character of the Irish fauna from a Lepidopterous point of view. This is discussed by the author in his introduction, in which he refers not only to the comparative poverty of the fauna, both as regards number of species and of individuals, even in comparison with England, but states that the climate has been so unfavourable to insects of late years that they have become still scarcer than before, while some species, formerly common in certain localities, have apparently disappeared entirely. On p. xviii. the author alludes to his having assisted Colonel Cooper in 1885, 1886 and 1887 in the attempt to introduce various Continental species into Sligo, experiments which, happily, failed. He adds: "The attempted acclimatisation of such exotics as the above I consider wholly unobjectionable, since if it were successful, none of the species could have been mistaken for natives." Among these "unobjectionable species" was *Porthetria* (or *Liparis*) *dispar*, the gipsy moth, the introduction of which might have been one of the most grievous calamities that has befallen Ireland for many years; and this gives us the opportunity of suggesting that the Government should absolutely prohibit the rearing of any species in the open which are known to be destructive abroad, notwithstanding their being rare or unknown in the British Islands; while a specially heavy penalty should be attached to the introduction of living specimens in any stage or for any purpose of such species as *Liparis dispar*, as in the case of the not more destructive Colorado potato beetle. What would Colonel Cooper have thought if in a few years he had found that the whole of his forests were being stripped of their leaves by the larvæ of *Liparis dispar*, as might easily have been the case had the climate and conditions proved favourable to the insect?

An Atlas of the Medulla and Midbrain. By Florence R. Sabin. Pp. 123; 7 coloured plates, one black plate and 52 figures. (Baltimore, Md., U.S.A.: The Friedenwald Company, 1901.) Price 1·75 dollars.

THIS book consists of a detailed account of a model of the medulla oblongata, pons Varolii and mesencephalon, which was made in the anatomical laboratory of the Johns Hopkins University by a reconstruction in wax of every alternate slice of a series of horizontal sections of the brain-stem of a new-born babe. The sections had been stained by the method of Weigert, so as to differentiate clearly the various nerve tracts, which are so distinct, the one from another, at the time of birth.

In the reconstruction only the important nerve tracts and the compact masses of grey matter have been represented, so that a glance at the model reveals the exact shape and relations of the peculiarly-contorted grey-masses and intertwining fibre-tracts, and enables the student to form an accurate mental picture of the most complicated and difficult region of the brain, such as no other method of study can convey.

Miss Sabin has carried out the arduous and laborious task of building the reconstruction in a manner so careful and patently successful that for the first time an accurate and trustworthy model is provided of a region which so many people have hitherto attempted to represent graphically by less tedious and correspondingly more inaccurate means.

The series of drawings representing the wax reconstruction has been so happily executed by Mr. Max Brödel that the model itself is hardly necessary.

Miss Sabin's description is full and complete and is illustrated by a large number of drawings both of the horizontal sections, from which the model was built up, as well as a "control series" of transverse sections of another brain-stem of the same age.

The view obtained of familiar structures is so novel, and one's attention so riveted in the mental accommodation, that the reader hardly looks for new observations. Nevertheless, the author has not only critically summarised the current literature of the structure of the medulla, pons and midbrain, but has also added to our knowledge of these regions.

The bibliography, which is intended for students, attains the happy mean of being sufficient without being bewildering.

In a work which is so happily conceived and so admirably executed there is little call for criticism. In perusing the work we noticed only one misprint. One of the figures (Fig. 50) has been misplaced; and it would be of considerable advantage to the student if Plate viii. were inverted so that the parts might be placed as they are in the body (and in Plate iii.).

This book and the model which it describes must convince anyone, who has carefully studied the structure of the brain-stem by means of the examination of sections, of the inadequacy of the conception of this complex region which he can acquire by such means; and it will be an invaluable aid for conveying to students an accurate understanding of this important part of the brain, which could not otherwise be acquired even by months of careful study. G. E. S.

Les Variations de Longeur des Glaciers. By Charles Rabot. Pp. 250. (Geneva: Georg and Co., 1900.)

THE study of the variations in the lengths of glaciers is one that has formed the object of investigation of many workers, and as the subject, besides being of considerable interest, is one in which exact information is very difficult to secure, various opinions may be formed as to the lengths of the periods of variations deduced.

What is therefore wanted to render deductions more exact is a great number of observations, spread over a considerable interval of time, and the more the observa-

tions can be made on a uniform plan, the more accurate will be the results obtained.

In February 1897, M. Rabot published the first part of the present work on the variations of the lengths of glaciers in the temperate and Arctic regions, and since that time the subject has been taken up by several other enthusiastic workers, so that now important information has accumulated. Thus Prof. Erich von Drygalski has made a study of the glaciers in Greenland, Prof. E. Richter has worked at the glaciers in Norway, while Mr. Israel Russell has confined his attention to North America.

In the book before us M. Rabot brings together all the data concerning the measures and appearances of the glaciers in the Arctic and temperate regions, giving references in each case to the original source of information. In the last chapter he brings together the conclusions to which he has arrived, but the reader must be referred to the book itself for a full account of them. The main results may, however, be here briefly expressed, and they are as follows :—

Prior to the eighteenth century, glaciers were much less extensive than they are to-day. During the eighteenth century and up to the first years of the nineteenth, an enormous increase, surpassing the amplitude of a single variation, occurred. Glaciers invaded territories which had never been previously occupied. This increase was general and affected all those in the northern hemisphere. During the nineteenth century the variation was indecisive. In some regions a considerable increase followed by a slight diminution in glaciation was noted, while in others the glaciers, after having remained at a maximum up till nearly the end of the century, diminished slightly. In no part was there such a considerable regression observed as that recorded in the Alps during the last fifty years.

With regard to the question of the oscillations of the lengths of glaciers in consequence of the variations of climate, which Prof. Richter has indicated does occur in the case of the Alpine glaciers, M. Rabot suggests that our knowledge is at present too incomplete to settle such a point with certainty.

Before bringing these remarks to a conclusion it may be added that this important work adds much to the advancement of our knowledge of the secular variations of the lengths of glaciers, and M. Rabot is to be congratulated on the important part he has so successfully played in its production.

Experimental Hygiene. By A. T. Simmons, B.Sc., and E. Stenhouse, B.Sc. Pp. viii+322. (London: Macmillan and Co., Ltd., 1901.) Price 2*s.* 6*d.*

IN their preface the authors state that the value of an introduction to the scientific method in the school training of both sexes is now recognised. That is so; but the scope and treatment of this scientific matter is the subject of a considerable amount of controversy at the present time among different authorities. Certainly no more suitable means exist of illustrating physical and chemical laws than by demonstrating their operation in the ordinary every-day occurrences with which the student is familiar.

It is no exaggeration to say that without some scientific knowledge the intelligent appreciation of the principles of hygiene and domestic economy is impossible. The writers of the work are therefore to be congratulated on having undertaken it with so excellent a motive, and one turns with considerable interest to the subject-matter to see how far they may be judged to have attained their object.

By the authors' scheme each subject is dealt with by first describing a few simple experiments and their results, then the physical and chemical principles responsible for those results are explained, and lastly it is pointed out how these principles are applied, or how they serve to explain certain every-day occurrences. At the end of each chapter there is a brief summary of the facts therein dealt with, and a series of exercises are then set out for the student. The book is well balanced throughout in its treatment of a large variety of scientific facts, and the matter is sound and well selected. The sole instance which we have noted in which exception may be taken to the teaching has reference to a simple means of filtering water. On pp. 148–149 the student is advised to clean a flower-pot and plug the hole at the bottom with a piece of sponge, then to place sand, with pebbles or charcoal, into the pot. Such a filter would not be efficient, and the householder would be safer if in his wisdom he preferred to drink the unfiltered water rather than make use of it.

The book concludes with an excellent chapter upon micro-organisms, where, in only nine pages, an account is given of those interesting growths which well meets the requirements of such a work. It is, in short, just sufficient to give the student an intelligent appreciation of what germs are. The book can be confidently recommended. It is of a handy size and well printed and bound.

Dictionary of Philosophy and Psychology. Edited by J. M. Baldwin. Vol. i. Pp. xxiv+644 (A—Laws of Thought). (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1901.) Price 21*s.* net.

THIS long-promised work will be of the highest value to every worker in fields which are in any way touched by psychological or philosophical thought. The contributors are almost all men of the highest eminence in their subjects, and the general editor has long been known as one of the ablest of the younger American psychologists. Some of the longer articles (*e.g.* "Brain") are really scientific treatises in miniature; where brevity is possible the articles are most laudably brief. A particularly valuable feature of the work is the series of monographs on philosophical terminology (arts. "Greek Terminology," "Hegel's Terminology," "Kant's Terminology"), by Prof. Royce, of Harvard. The outward appearance and the typography of the book reflect the greatest credit on the publishers and the Oxford University Press.

The end of the alphabet is to be reached in vol. ii., and vol. iii. will consist of a series of full bibliographies of the various departments of philosophical and psychological literature. A. E. T.

Die Vogelwelt des Amazonenströmes; Enstanden als Atlas zu dem Werke "Aves do Brazil." Von Dr. Emil A. Goeldi (1894–1900). Part i. (Zurich: Polygraphischen Institut, 1900.)

WE have received from the Polygraphischen Institut of Zurich a copy of the first part of this atlas, which is merely a replica in German of the one noticed in our issue of August 22, 1901, under its Portuguese title of "Album de Aves Amazonicas." In fact, it is only the cover that has been altered, the descriptions of the plates themselves remaining in the original Portuguese. We have nothing to add to the remarks made in the notice referred to, except that the plates are excellent examples of three-colour printing.

The Betteswortk Book. Talks with a Surrey Peasant. By George Bourne. Pp. vi + 325. (London: Lamley and Co., 1901.) Price 5*s.* net.

FROM a scientific point of view there is little of interest in this book, but as a realistic record of the thoughts and experiences of a Surrey labourer, reproducing more or less the dialect of the county, the conversations are certainly worth preserving. There is no attempt at fine

language or refined rhapsodies on rural life and scenes, but in natural vigorous words Bettesworth—that was the name of the labourer—gives his opinion upon sundry persons, places and things he has known. The ethnographer will here and there find descriptions of country customs and remedies which will interest him.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Relative Velocity in Streams.

IN your review of the report of M. Vallot from his observatory on Mont Blanc (p. 31) you speak of his finding that a stream ceases to increase in speed in a channel of greater incline than 3 in 100 as something unexpected.

For more than twenty years I have contended, in repeated publications, that friction against the bed increasing progressively from the middle to the margin divides every stream longitudinally into two halves, which roll spirally toward each other. This spiral being determined by the friction, its helix rises with the speed, or the increased friction depending on the speed, which in turn depends on the slope of the channel. It follows that beyond a certain speed the stream loses all the momentum gained by its fall in beating with the two outward-moving undercurrents against the channel walls. In this way the stream attains its kinetic equilibrium. If glaciers are plastic or viscous bodies, they, too, must obey the same laws.

Louisville, Kentucky, U.S.A. D. T. SMITH.

Change of Pitch of Certain Sounds with Distance.

IN NATURE of December 12 (p. 129), Mr. F. M. West describes an observation made while walking up and down the platform of a railway station. The pitch of the sound caused by the steam escaping from an engine rose as he retreated from it and fell as he drew near to it.

As I gave the explanation of the same phenomenon in *Les Archives Néerlandaises* (Arch. Néerl. Livre jubilaire, November 1901), I may be permitted to give a summary in these pages.

The pitch will not only rise by retreating from the engine, but also by bringing the ear nearer to the ground. The pitch is due to reflection of the sound from the platform itself, for when a large board is laid down on the ground between the engine and the observer, the pitch will be heard to rise when the board is raised.

It is clear, therefore, that the pitch can be caused by interference of the direct and the reflected sound-waves, a phenomenon wholly similar to Lloyd's experiment with light-waves. As in Lloyd's experiment the elementary colours of the white light are separated in space, so here the different pitches of sound will predominate in different points of space, and a sort of sound-spectrum will be formed.

A mathematical examination enables us to analyse the irregular vibration of a noise during a short time, according to Fourier, into a series of harmonic vibrations. Moreover, it can be proved by calculation that the interference of the direct and the reflected sound-waves must cause at any spot a series of (impure) pitches to be heard. The wave-lengths of these pitches must be 1/1, 1/2, 1/3 . . . of the difference of distance travelled over by both sounds.

An experimental examination, made at the platform of a railway station, has shown me that the pitch of the noise of an engine fully agrees with the theory, so far as the impurity of the pitch permitted an exact experiment to be made.

When the noise of a waterfall or rustling trees is perpendicularly reflected by a wall, Baumgarten has observed the change of pitch in the vicinity of this wall (Müller-Pouillet, "Lehrbuch der Physik," i. p. 732). The above-mentioned result is also applicable in this case. In the neighbourhood of a waterfall I obtained experimental results perfectly agreeing with theory.

D. VAN GULIK.

Apeldoorn, December 15.

CHEMICAL INSTRUCTION AND CHEMICAL INDUSTRIES IN GERMANY.

JUST now, when men of science and educationists are continually directing attention to the superiority of German educational and industrial methods, especially in the domain of chemistry, a report published among the "Miscellaneous Series" of the Foreign Office is most apposite, and should be studied by all who are truly interested in the educational and commercial welfare of the nation.

The object of the report, which is compiled by Dr. Frederick Rose, His Majesty's Consul at Stuttgart, is "to show to what extent the German chemical industries have benefited by the sums expended by the German States on chemical instruction." A perusal of the contents of this highly interesting and instructive report shows us that the German technical high schools or polytechnics differ *in toto* from those of the United Kingdom. They are, in fact, more like our University colleges, *e.g.* Owens College and Mason College (new University of Birmingham). The older Universities in Germany began to study chemical technology about the middle of the seventeenth century. They thus laid the foundation-stone of the present-day industrial chemistry for which the country has become famous. As trade and chemical industries gradually advanced, the Universities were found inadequate to train the greatly increased number of chemists who were required. The polytechnics (now called technical high schools) were consequently founded. These are, without exception, products of the nineteenth century. One must not, however, lose sight of the fact that it is only within the last two generations that the technical high schools have assumed such prominence. They had first to learn what was required of them if they were to exert a really beneficial effect upon the welfare of the country. On p. 8 of the report the following words appear, which we trust some of our technical educationists will take to heart:—

"The study of architecture, engineering and chemistry at the technical high schools left, at the beginning, much to be desired, as the erroneous opinion prevailed that it was not necessary for the students to devote themselves to the study of scientific works, but rather to acquire a certain practical aptitude in superficial manipulation. . . . Later on, however, it was clearly perceived that the scientific foundation laid during the scientific courses at the technical high schools formed the soundest basis for the practical experience to be gained during professional life."

In the British polytechnics the teaching staff have no social status, and the scale of remuneration depends entirely upon the governing body, who have usually great difficulty in making both ends meet. But in the Prussian technical high schools, which are under the direct control of the State, the members of the professional staff possess the rank of full State officials, and the salaries are regulated according to certain fixed limits. Indeed, so deeply is the German Emperor convinced of the importance of technical education that he has caused the directors of the Prussian technical high schools to be admitted to the Prussian Upper House, while a short time ago at the centenary of the Berlin Technical High School he conferred upon the Prussian technical high schools the right to confer a new degree of Doctor of Engineering, thus practically raising the technical schools to the level of the Universities.

Before the students are allowed to pass into the technical high schools they must show that they have obtained a preliminary education of a very high order. Whilst it is no unusual thing in our polytechnics to find students who have absolutely no knowledge of the merest elements of arithmetic and who are quite unable

to enter the results of their experimental work in an intelligible manner, such students could not enter the German technical high schools.

Students of chemistry who enter the technical high schools do not devote the whole of their time to chemistry; they take out a full technological course, including such subjects as trigonometry, higher mathematics, physics, botany, electrotechnics, technical drawing, machine drawing, &c. The above subjects have been taken at random from the syllabus of the Darmstadt Technical High School for 1895. Perhaps, however, the thoroughness of the courses through which the student must pass before obtaining his technological diploma is best shown by a study of the syllabus of the Stuttgart Technical High School.

Any extra time at the students' disposal is devoted to practical chemistry, bacteriology, or the chemistry of foods, &c.

The pioneering labours of the German Universities are known to everyone. For pure chemical research they have obtained for themselves a position which places them almost above criticism, and which has made them the envy of the world, insomuch that students flock to them from all countries. In 1897 there were 13,000 students at the Prussian Universities; of these 9 per cent. were foreigners. Each of these students costs the State 31*l.* annually, or about 36,000*l.* In the Prussian high schools during the same year there were 4246 students, of whom 13 per cent. were foreigners, costing the State 14*l.* per head, or nearly 8000*l.* That is to say, in 1897 the Prussian State expended 43,000*l.* on the education of foreigners, many of whom would in all probability enter into trade competition with themselves. Taking the whole of Germany into account it is calculated that no less than 60,000*l.*, or the interest on 2,000,000*l.*, was expended in educating foreigners.

In one respect the German Universities and polytechnics possess an enormous advantage over those of this country—*they are not hampered by want of funds.* The German Government realises the importance of education, hence the Universities and technical high schools are built upon the most modern principles and fitted up in a style which is little short of perfection. It must not, however, be denied that here we also build and fit up polytechnics in a manner which leaves little to be desired, so far as the external structure and paint and varnish are concerned. But it so often happens that all the funds have been swallowed up by bricks and mortar, hence there is no money forthcoming for adequate equipment and maintenance,[1] much less for research. The result is, the teaching staff is miserably inadequate and consequently overworked.

The following table, the numbers in which are taken from the reports from University colleges, issued by the Education Department, gives the income and the Government grant for five of our University colleges for the year ending July 31, 1899:—

	Income.		Government Grant.
	£		£
King's College, London ...	42,369	...	2200
University College, London	35,456	...	3000
Owens College	47,494	...	3500
University College, Liverpool	23,792	...	3000
Mason College, Birmingham	17,864[2]	...	2700[2]

Contrast this with the German Universities and technical high schools; for our Universities and University colleges, as well as our polytechnics, are but too often without sufficient income.

In 1899 the total income of the University of Berlin was 143,555*l.*; of this large sum no less than 83 per cent. was contributed by the State, while 80 per cent. of the income of the University of Bonn (63,037*l.*) was obtained from the Government. Turning to the technical high schools, that of Berlin, with a total income of 69,077*l.*, received 33,675*l.*; Hanover, total income 25,240*l.*, obtained 15,094*l.*; while Aachen, having an income of 22,998*l.*, received 16,581*l.* from the Government. The teaching staff of the chemistry department—I have not the numbers for the other departments—is also on an equally lavish scale, as the appended table shows:—

		Teaching Staff.		Students.
Heidelberg University	...	10	...	315
Strasburg University	...	7	...	48
Berlin Polytechnic ...	...	44	...	278
Stuttgart Polytechnic	...	10	...	88
Karlsruhe Polytechnic	...	15	...	139

It has already been mentioned that the technical high schools are taking a more and more leading place; this is shown by the fact that during the last seventeen years the students at the technical high schools have increased 206 per cent., whereas at the Universities the increase is only 12 per cent. In some chemical works preference is given to students who have studied at the technical high schools, one reason being that technical high schools devote much more attention to the teaching of technology. It is estimated that there are in Germany about 4500 trained chemists who have had the full courses at the Universities or technical high schools. But notwithstanding this vast array of expert technical chemists and the preeminent place which German chemical industries have obtained, in chemical industrial circles in Germany there is a widespread feeling that there must be no resting on their oars, but that increased facilities for technical education must be obtained, and it is felt that, unless the Universities devote more attention to technology, the diminution in the number of students will in the course of ten or fifteen years react most unfavourably upon the German chemical industries. How much more so is this the case in our own country, where chemical technology is rarely taught? At our Universities and polytechnics we appoint *one* professor, who has to teach all the branches of chemistry. In Germany there is a professor set apart to teach technology, a

[1] The Technical Education Board of London do their best to remedy defects in equipment, but their funds are not unlimited, and it is not their province to pay for the general upkeep of the institutions.

[2] This does not include the day training college, which has an income of 5400*l.* and 3679*l.* in the form of grants from the Education Department.

special lecturer for physical chemistry, and very often a professor for organic and another for inorganic chemistry, beside numerous lecturers on different branches of the subject.

The German nation, which has placed its primary and technical education on a sound basis, has been richly rewarded. In 1897 the total production of the German chemical works was 47,391,132*l*. Within the last twenty years many new and flourishing industries have been started, the foundation of which has been entirely due to the results of chemical research. Again, one has only to glance at the appended list, which shows the dividends of some of the larger chemical works, all of which employ a large staff of fully trained chemists, to recognise that science and successful commerce go hand-in-hand:—

Name of works	Dividends 1893 Per cent.	1896 Per cent.	1899 Per cent.
Höchst Colour Works	28	28	26
Baden Aniline and Soda Works	27	26	24
Elberfeld Colour Works	18	18	18
Schering and Co., Berlin	19	11	12
Nobel and Co., Hamburg	21½	13	18
Munich Paper Works	15	16	18
Rositz Sugar Works	3	12	13

In this country the Government relies too much upon private initiative and individual generosity. Because nearly all the pioneering labour and many of the most brilliant scientific results of the past century have, so far as this country is concerned, been conducted by private individuals who were fired with the restless and resistless energy of genius, the Government and the manufacturers wrap themselves in an impenetrable armour of self-complacency and blind optimism. Our forefathers, they say, had practically no scientific education, and see how they excelled in invention and obtained the control of the commercial world. Let them, however, remember that in those days the Germans had also practically no scientific education, neither was their empire consolidated as it is at the present moment. So long as the Government refuses to recognise the needs of science, and manufacturers, with fatuous obstinacy, refusing to learn from the experience of other nations, look upon chemists as expensive luxuries, so long will chemical trade remain in the hand of our rivals.

F. MOLLWO PERKIN.

THE GEOLOGICAL SURVEY OF THE UNITED STATES.

IN NATURE for December 27, 1900, we noticed the first and sixth parts of the Twentieth Annual Report of the United States Geological Survey. We have now received the remaining volumes. Part ii., comprising "General Geology and Palæontology," consists of 953 pages with 193 plates. It includes a brief article on the geology of the Philippine Islands, by Mr. G. F. Becker; but as we have since received the full report (noticed further on), we may pass on to the next paper by Mr. J. Nelson Dale, a study of Bird Mountain, Vermont. This mountain, the summit of which is 2200 feet high, lies in the Taconic Range, and consists of about 500 feet of Ordovician grit and conglomerate interbedded with muscovite-schist, and underlain by similar schist with beds of quartzite. The author discusses the origin of the mountain, the features of which have been largely sculptured by glacial action. The Devonian fossils from south-western Colorado, constituting the fauna of the Ouray Limestone, are described by Mr. George H. Girty. Although by some authorities regarded as Carboniferous, Mr. Girty considers that the fauna indicates late Middle or early Upper Devonian. Varieties of *Spirifer disjunctus* occur, together with numerous other fossils.

A preliminary paper on the geology of the Cascade Mountains in Northern Washington is contributed by Mr. Israel C. Russell. The rocks comprise granite, various schists, greenstone and serpentine of unknown age, and also a great extent of slightly altered and unaltered sedimentary strata, mainly Cretaceous and Tertiary, with some possibly of Jura-Trias age. The granites and allied rocks are usually jointed in a conspicuous manner. The influences of these joints on the rugged spires and cathedral-like forms resulting from weathering are among the most characteristic details in the magnificent scenery of the Cascade Mountains. The structure of the range is highly complex. This is briefly described, and fuller particulars are given of the striking effects of glaciation.

Mr. Lester F. Ward is the author of an elaborate essay on the older Mesozoic floras of the United States, Triassic and Jurassic; and Mr. David White deals with the stratigraphic succession of the fossil floras of the Pottsville formation in the southern anthracite coal-field of Pennsylvania. The plants of this Carboniferous formation exhibit a rapid development, and a series of changes or modifications, which are considered of high stratigraphic value.

Part iii. deals with the "Precious-metal Mining Districts." The Bohemia mining region of western Oregon is described by Mr. J. S. Diller. It is situated at an altitude of between 4000 and 6000 feet above the sea, along the crest of the Calapooya Mountain, and upon both slopes. The mountain is composed of lavas like those of the Cascade Range. Generally the sheets of lava are very irregular. The lava filling the throat of a once active volcano has in the case of the Cougar Rock made a prominent peak, while in Bear Bones Rock it presents a conspicuous columnar structure. The streams have cut deep, narrow valleys, approaching canyons in character. These expose rocks to a depth of more than 2000 feet—comprising lavas (chiefly andesites), vein matter and stratified fragmental volcanic material. It is probable that volcanoes were active in Eocene times, and continued so during the Miocene period. The veins lie along narrow, irregular joint-planes in which there has been much crushing of rock material. The principal gangue is quartz, containing at a depth much pyrites and other sulphides in which gold occurs; while near the surface the gold is native, finely filamentous and distributed through iron-stained quartz. The output in this region has been chiefly from one mine during the last few years. Mr. F. H. Knowlton contributes an account of the Miocene plants of the Cascade Range.

The gold and silver veins of Silver City, De Lamar, and other mining districts in western-central Idaho are reported on by Mr. Waldemar Lindgren. The area includes four types of scenery: (1) the Snake River valley, extensive arid plains underlain by Neocene lake-beds with intercalated flows of basalt, which are cut into to a depth of from 400 to 1000 feet; (2) the Owyhee Range, a steep granite ridge covered by broad areas of Neocene lavas; (3) a great central granite region north of the Snake River, with bordering sedimentary rocks, probably Palæozoic, showing extensive contact metamorphism: the whole described as a veritable labyrinth of ridges and peaks separated by sharply-cut canyons, the higher ridges attaining elevations of 12,000 feet, and evidently an old plateau with an intricate and deeply-cut drainage system; and (4) a more recent plateau of the Columbia lava flows, of Miocene age.

The mineral deposits of the great granite area are fissure veins, containing gold and silver in a quartzose gangue. The adjoining sedimentary areas carry either veins or contact deposits of irregular shape, generally containing silver, lead, zinc and copper. The Tertiary volcanic rocks contain in places gold and silver veins

of peculiar character. Considerable amounts of placer deposits are found in the gravels associated with the Neocene lake-beds. It is considered that some of the mineral veins may be of Cretaceous or Eocene age, some may be older, and others are post-Miocene.

Mr. W. H. Weed describes the geology of the Little Belt Mountains, Montana, an elevated and eroded plateau region. Gneisses and schists form a central core, upon which rest a great variety of sedimentary rocks, penetrated by igneous rocks, which appear as dykes, sills and laccolites. Silver-lead ores, gold, iron ores and sapphire mines are described. The petrography of the igneous rocks is dealt with by Mr. L. V. Pirsson, who describes syenite, monzonite, shonkinite (a basic granitoid rock) and many other rocks. The rock in which the sapphires occur is allied to the minettes and shonkinite, and it appears to have derived its alumina from clay-shales through which it was intruded; the molten rock on its way incorporating shale-fragments in its mass. The many subjects dealt with in this elaborate memoir are fully illustrated with views, diagrams and plates of microscopic sections of rocks.

Part iv., on "Hydrography," deals with stream measurements and reservoir sites, and there is a special article on Nicaragua. The volume is well illustrated with views and diagrams. Part v. is on "Forest Reserves," and has excellent maps, views of scenery and woodland, and notes on soils and timber-trees. Part vii., "Explorations in Alaska," is a volume of more than 500 pages, profusely illustrated, and dealing with the topography, geology, agriculture, game, and inhabitants.

Mr. George H. Eldridge gives an account of a reconnaissance in the Sushitna Basin and adjacent territory. Here the geological formations include granite, schists and slates, and a series of conglomerates and sandstones of undetermined age; also sandstones and shales with coal-seams belonging to the Eocene; and sundry Drift deposits. Traces of gold occur in the pyritiferous quartz of the slate series, but elsewhere in placer deposits. The coal is a low-grade lignite.

Mr. J. E. Spurr deals with south-western Alaska, and his report is accompanied by a coloured geological map showing gneiss and schists, Silurian, Carboniferous-Devonian, Jurassic, Cretaceous, Eocene and later deposits, as well as Tertiary intrusive and volcanic rocks. He describes as fully as possible the sedimentary and eruptive rocks, and with regard to the latter employs the name Alaskite group for certain quartz-alkali-felspar rocks, and Belugite group for rocks transitional between the diabasic and dioritic families.

Mr. W. C. Mendenhall describes the country from Resurrection Bay to the Tanana River; Mr. F. C. Schrader deals with a part of Prince William Sound and the Copper River district; and Mr. A. H. Brooks with the White and Tanana River basins.

One general conclusion is that Alaska is eminently not the place for the haphazard or untrained prospector; and that in the long run only those who have the intelligence, training, and patience to study the conditions of the occurrence of gold can hope to succeed.

We have received the first and sixth parts of the Twenty-first Annual Report. In Part i. the director, Mr. Charles D. Walcott, refers to the reorganisation of the geological branch which came into effect in July 1900. The need was felt of closer and permanent supervision in scientific lines, and the Geological Survey was subdivided and each division placed in charge of a specialist as follows:—Areal Geology (stratigraphy, structure and pre-Pleistocene physiography), Bailey Willis; Pleistocene Geology, T. C. Chamberlin; Palæontology, T. W. Stanton; pre-Cambrian and Metamorphic Geology, C. R. Van Hise; Mining and Mineral Resources (distribution and production of economic minerals), D. T. Day; Economic Geology (metalliferous ores), S. F. Emmons (non-metalliferous deposits, &c.), C. W. Hayes; Physical and Chemical Research, G. F. Becher. Accompanying this volume is an obituary notice of Prof. O. C. Marsh, prepared by Mr. Arnold Hague.

Part vi. consists of two volumes, dealing with mineral resources. The great demand for mineral products led to an increase in 1899 over 1898 of more than 10 per cent. in output and of more than 39 per cent. in value. Nearly every important "mineral" participated in this increase, notably pig iron, copper, coal, natural gas, petroleum, cement and stone. Lead showed a decline. The value of grindstones was large and that of oilstones and whetstones the largest on record. Pigments, again, were in great demand. Fuller's earth was produced in less quantity and more was imported; it is used partly for decolorising vegetable oils.

We have also received a reprint from the Twenty-first Annual Report, Part iii. (1901)—a Report on the Geology of the Philippine Islands, by Mr. George F. Becker, with notes on the Tertiary fossils, by Mr. K. Martin. In these islands schists and massive crystalline rocks occur, together with diorites, diabases, and gabbros. Of newer volcanic rocks there are basalt, andesite, dacite, and probably trachyte and rhyolite. A considerable number of volcanoes have ejected ash and lava recently, or since the occupation of the country by the Spaniards. Tertiary strata from Eocene upwards are well developed in the islands, but have been imperfectly studied. Of mineral resources there is a brown coal of Tertiary age, while gold-mining is an ancient industry. Even the tricks of the trade are not unknown to the natives, and they "nearly succeeded in inducing some American officers to take an interest in gravel salted with brass filings." The auriferous deposits include veins, placers, and river sands. The occurrence of copper, argentiferous lead-ore, and magnetic iron-ore is noticed.

In addition to the Reports already mentioned, we have received Nos. 163 to 176 of the *Bulletin* of the United States Geological Survey, all published in 1900. These deal with a variety of subjects, and not the least useful is that by Mr. F. B. Weeks (No. 172)—a bibliography of American geology for 1899, in which 799 articles are listed and indexed.

Of purely geological articles we have a reconnaissance in the Rio Grande coal-fields of Texas (No. 164), by Mr. T. V. Vaughan. Although the State is by far the largest in the Union, embracing a quarter of a million square miles of territory, it stands low in the scale of coal producers. The coals occur in strata of Upper Cretaceous and Eocene age, and they vary in thickness from a few inches up to 7 feet. Details are given of the strata and their fossils, and it is remarked that there are not yet sufficient data to trace accurately the boundary between the Cretaceous and Eocene. The Cretaceous coals of the Eagle Pass coal-field are regarded as of anthracitic type, and as by far the best fuel in America except the true anthracites of Pennsylvania. The Eocene coal is strictly speaking a lignite. Mr. E. C. E. Lord contributes a report on the igneous rocks of the San Carlos coal-field. These rocks indicate late Cretaceous or early Tertiary lava flows, and comprise rhyolite breccia, quartz-pantellerite, and basalt.

Contributions to the geology of Maine are made (in No. 165) by Mr. H. S. Williams and Mr. H. E. Gregory. Mr. Williams deals with the Silurian and Devonian faunas, and enters into a discussion of the characters and evolution of the Rhynchonellas. He remarks that there is no question as to the great importance of internal characters for purposes of determining the genetic relationship of organisms; but it is also a fact that the external characters do not cease to be of similar value. He points out that the taxonomic rank of characters rests

primarily upon their relative fixity, and not upon their supposed importance in the individual economy of the organism. Generic characters to be of taxonomic value must be distinguished from varietal and specific characters by their greater fixity, or what may be defined as their more exact reproduction or transmission in generation. He further remarks that the attempt closely to correlate specimens with some particular species diverts the attention from the evolutional laws which the evidence contains and illustrates. The study of a single group of species demonstrates the fact that the evolutional stage of the group is indicated with precision, independent of the names of the species, and independent of the fact that the specimens actually present in the Maine fauna agree precisely in scarcely a single case with those of any fauna in New York.

Mr. Gregory reports on the geology of the Aroostook volcanic area. North-eastern Maine is essentially a region of sedimentary rocks, with prominent exposures of igneous rocks in Castle Hill and Mapleton townships. This area appears to have been a distinct centre of volcanic activity. Rhyolites, trachytes and andesites are described. Elsewhere there are tracts of granite and other igneous rocks.

Of purely palæontological papers there is an account of the flora of the Montana formation (No. 163) by Mr. F. H. Knowlton. The formation is approximately of Laramie (late Cretaceous) age. There is also an elaborate synopsis of American fossil Bryozoa (No. 173) by Mr. J. M. Nickles and Mr. Ray S. Bassler.

Contributions to chemistry and mineralogy, with analyses of rocks, are given (in Nos. 167 and 168) by Mr. F. M. Clarke. Various crystalline and sedimentary rocks, soils, and meteorites, are dealt with. Mr. W. F. Hillebrand treats of some principles and methods of rock analysis (in No. 176). Of miscellaneous reports we have a gazetteer of Utah (No. 166), altitudes in Alaska (No. 169), and other topographical papers (Nos. 170, 171, 174 and 175).

Several Monographs published by the U.S. Geological Survey have also been received. Monograph No. 39 (1900) contains an account of the Eocene and Lower Oligocene Coral Faunas of the United States with descriptions of a few doubtfully Cretaceous species, by Mr. T. Wayland Vaughan. The author laments that the classification of corals is in a most unsatisfactory condition, but he has described his material with all possible care in the hope that ere long some one may be able to give a classification based on the actual phylogenetic grouping of the various genera. The larger the number of specimens the more difficult it is to define species: Mr. Vaughan has tried to be conservative, and when a form in one horizon grades into a form in the horizon next above, he has named them varieties of the same species, even when the variety possesses an individuality that makes it easily recognisable.

In Monograph No. 40 (1900) Mr. S. H. Scudder deals with certain Coleoptera from the Tertiary deposits at Florissant, Colorado, and gives a systematic list of the non-rhynchophorous Tertiary Coleoptera of North America.

NOTES.

H.R.H. THE PRINCE OF WALES has accepted the presidency of the Society of Arts, which was vacated by His Majesty the King on his accession.

DR. WILLIAM SOMERVILLE, late professor of agriculture at the University of Cambridge, has been appointed to be an assistant secretary to the Board of Agriculture in succession to Sir Jacob Wilson, who has retired.

DR. ARTHUR SMITH WOODWARD, F.R.S., has been appointed keeper of the Geological Department of the British Museum (Natural History), South Kensington, in succession to Dr. Henry Woodward, who retired on November 23 after a service of nearly forty-four years. Curiously enough, there is no family relationship between the present and past keepers.

MAJOR A. W. ALCOCK, F.R.S., Superintendent of the Indian Museum, Calcutta, informs us, that Mr. L. de Niceville died at Calcutta of fever contracted in the Darjeeling Terai, on December 3.

IT is announced by Dr. D. Morris that the fourth annual West Indian Agricultural Conference will be held at Barbados on January 4 and 6, 1902. The object of the conference, as laid down by the Secretary of State, is the reading of papers and discussion on the scientific and economic aspects of the sugar-cane and other industries. It is hoped that the subjects brought forward will be dealt with from a thoroughly practical point of view and with a full knowledge of the requirements and circumstances of each colony concerned.

THE death of Mr. James G. Shipman, F.G.S., deprives geological science of an ardent local worker, who did much to enlarge our knowledge of the rocks and fossils of the neighbourhood of Nottingham. He commenced life in comparatively humble circumstances; he was apprenticed to the printing trade, and was finally given a post on the sub-editorial staff of the Nottingham *Daily Express*. His interest in geology was aroused by lectures given more than thirty years ago by the late Edward Wilson. Thereafter he devoted himself to the subject with remarkable assiduity. His leisure hours were spent in studying all sections within reach of Nottingham, and he contributed a number of papers, chiefly on the Drift and Triassic deposits, to the Annual Report and *Transactions* of the Nottingham Naturalists' Society. Latterly he had paid much attention to the structure of the Nottingham and Derbyshire Coal-field, and had qualified himself to give expert advice on water-supply. He died on November 21, aged fifty-three.

A REUTER'S telegram states that Mr. William Bruce, the leader of the Scottish Antarctic expedition, has purchased the Norwegian steam whaler *Hecla* for his forthcoming expedition to South Polar regions. The *Antarctic*, with Prof. Nordenskjöld's South Polar expedition on board, left Buenos Ayres on Friday for the Falkland Islands. The *Discovery* left Lyttelton for Dunedin on Saturday afternoon, and has by now sailed for the Antarctic.

PROF. H. HERGESELL, president of the International Aëronautical Committee, informs us that arrangements are being made to continue the manned and unmanned balloon ascents during 1902, the dates proposed being the first Thursday in each month, except January, when the second Thursday is selected. Since November 7, 1900, 120 ascents have been made; the observations are now being discussed and will throw much light on the physics of the upper air. It is proposed to hold a meeting of the Committee next year in Berlin, when questions relating to new thermometers, observations of atmospheric electricity and magnetism will be discussed.

IN connection with the valuable series of forty years' observations taken at Camden Square (N.W. London), *Symons's Meteorological Magazine* for December contains the monthly results and extremes of solar temperatures for twenty-eight years commencing with 1870, made by both black and bright bulb radiation thermometers. The following are some of the values obtained by the black bulb *in vacuo*:—Highest monthly average, 123°·4, absolute maximum, 137°·7, both in July. Lowest monthly mean, 36°·9, absolute minimum, 24°·8, both in Decem-

ber. The absolute extremes by the bright bulb *in vacuo*—an instrument not in general use—were 105°·4 in July and 22°·5 in January.

THE fifth list of current papers collected and discussed by Mr. H. C. Russell, Government Astronomer of New South Wales, covers a period of thirteen months, from October, 1899, to November, 1900. No less than 448 papers were thrown overboard, mostly in the southern Indian Ocean, but only eighty-six of these were recovered; 106 papers were received during the period mentioned, but twenty of them had been more than thirteen months drifting. Three of the papers set afloat near the Cocos Islands landed on Africa and showed the high rates of 18·3, 20·6 and 25·4 miles a day, the latter being the record drift obtained by Mr. Russell. The following summary of the average drifts obtained in the Indian Ocean during the years 1893–1900 is very interesting:—from the equator to 10° S., 13·3 miles a day; from 10° to 30° S., 16·6 miles; from 33° to 43° S., 7·6 miles; from 43° to 50° S., 9·4 miles. Among the last series of papers, one thrown overboard off Cape Horn found its way to the west coast of Africa, in Ashantee, the drift in a straight line being 5350 miles in a N.N.W. direction, the rate per day being 10·1 miles. The track and daily position of the s.s. *Waikato* are shown on a chart and will be useful for other steamers which may have to drift in the same waters. This vessel broke her main shaft on June 5, 1899, in lat. 37° 30′ S., long. 21° 0′ E., and drifted about in the Indian Ocean until September 15, when her position was lat. 39° 29′ S., long. 64° 30′ E.

THE production of motive power from blast-furnace gases formed the subject of a paper by Mr. Bryan Donkin, read before the Institution of Civil Engineers on December 17. Only within the past few years has it been realised that power can be produced economically and effectively by utilising the gases from blast-furnaces to drive gas-engines. As the annual production of iron from blast-furnaces throughout the world is forty million tons, this new application of motive power is capable of immense development. The gases given off from these furnaces during the process of smelting iron are practically the same as weak producer-gas. Until within about half a century ago they were all wasted. A part was next utilised under boilers to generate steam to drive the blowing engines and part to heat the air-blast; but after supplying these requirements a considerable surplus was available. Successful efforts have been made, first to use this surplus in gas-engine cylinders, to obtain power, and next to discard steam-engines, boilers and chimneys entirely, and utilise all the gas in this way. A great impetus has been given to the construction of large motors by the discovery that blast-furnace gases can be used to drive them. They are now made in sizes up to 1000 h.p. and 1500 h.p., and still larger powers are in contemplation, while the difficulty of starting these large engines has been successfully overcome. Mr. Donkin gave some account of the very rapid progress made in this class of work on the continent. Many of the large firms in Germany and Belgium are now busily employed. The Gasmotoren-Fabrik Deutz has numerous orders for motors from 500 h.p. to 1000 h.p., while at Seraing, in Belgium, an aggregate of 39,000 h.p. has been bespoken. Messrs. Körting, of Hanover, have also supplied several engines, and the Deutsche Kraftgas-Gesellschaft propose to construct motors up to 1500 h.p. and 2000 h.p. It was remarked that England and Scotland seem rather slow to utilise these gases.

FROM an article in *Transport* it appears that oil has been very successfully used as fuel for steamers. An inspection of the *Clam* steamer, belonging to the Shell Transport Company, was recently made prior to her departure from the Thames for Philadelphia. It was shown from the vessel's log that for two years the steamer has been using oil instead of coal, and that it was found that eighteen tons of oil gave off more heat than twenty-eight tons of coal, and with improvements recently made it was expected that still better results would be obtained. The employment of liquid fuel also led to a considerable economy of labour, got rid of many of the difficulties attending the stokehold, and allowed a considerable addition to the space available for cargo. The *Clam* has relied solely upon obtaining a supply of oil from Borneo, and the company claim that from their wells in that country they can supply 100,000 tons of oil a day. The company are so satisfied with the results obtained that they intend to send to sea a fleet of eighteen steamers burning oil as fuel. In the United States oil is very largely superseding coal for locomotive engines, especially for street railways. In this country the Great Eastern Railway Company have many of their engines fitted for using oil as fuel, the advantage of which was found very great during the late high price of coal.

THE feature of the North Atlantic and Mediterranean pilot chart for January, issued by the Meteorological Office, is the introduction of the curves of equal magnetic variation for the whole of the sea space. They are for the year 1905, and are drawn for each 2°. This addition makes the charts far more complete, and it will be greatly appreciated by mariners and others. In some quarters the numerous wrecks occurring on the Newfoundland coast have been attributed to errors in the variation in that locality, but it is pointed out that it is sufficiently accurately determined for navigational purposes. The very variable currents experienced in the neighbourhood are the most probable cause of so many disasters, and during the prevalence of thick weather mariners are therefore urged on no account to neglect the use of the lead, as it is impossible to foretell with certainty how the current has been running, the prevailing southerly set being sometimes replaced by a north-going one, which would tend to drift a vessel up the coast between Cape Race and St. John's. Being midwinter, fog is by no means frequent on the banks, barely exceeding 10 per cent. of the weather observations. It is, however, interesting to notice that the season of least fog in the Newfoundland region is the season of greatest frequency of dense "red dust" clouds on the eastern side of the ocean, off Africa. Four years ago the Cape liners were delayed as much as three days by a thick dust fog, which extended for a distance of about 2000 miles southward from Madeira. The coasts of Trinidad and Guiana are at this season subject to rollers, which are dangerous to heavily laden small craft. There are some notes on the more salient features of the currents in various localities; the anti-cyclonic type of weather over western Europe is illustrated by an inset chart, the remarks showing that in January the barometer may rise as high as 31·1 in. within the British Isles; and the prevailing winds and the movements of the centres of cyclonic systems in the Mediterranean region during January are explained.

WE have received a copy of the tide table for Halifax, Quebec, St. John (N.B.) and Father Point, issued by the Tidal Survey branch of the Department of Marine and Fisheries, Canada, for the year 1902. This contains extended new information on the tides and currents of the St. Lawrence, based upon investigations made by the Tidal Survey in the season of 1900.

HERR H. WIECHEL contributes to the *Proceedings* of the "Isis" Natural History Society in Dresden an interesting paper on the ancient roads of Saxony. A sketch-map, elaborated from the "Oberreit'schen" atlas, which is based on the engineer surveys of about the year 1780, shows the chief roadways existing during the period A.D. 800 to 1200, and the paper discusses the routes, topographical names, &c., in detail.

UNTIL a few months ago, Tahiti could be reached from the United States only by a sailing schooner from San Francisco in a voyage of six or seven weeks. The French Government has now arranged for a steamship to leave San Francisco for Tahiti every five weeks, and as the voyage only lasts about eleven days, many travellers will probably take advantage of it. The development of means of communication will, however, produce decided changes in the ways and customs of the natives, and this induced Dr. S. P. Langley to visit Tahiti by the first trip of the new line. An interesting diary of the voyage and visit kept by him is printed, with illustrations, in the December number of the *National Geographic Magazine*. It will be remembered that Dr. Langley described in NATURE, of August 22 (vol. lxiv. p. 397), the fire-walk ceremony witnessed by him during his visit; and his observations showed conclusively that the alleged miraculous power of resisting fire possessed by the performers has no foundation in fact. The success of the fire-walk depends upon the low thermal conductivity of the stones among which the fire is kindled, as Dr. Langley explained in his letter to NATURE, and describes in his diary. Other ordeals by fire, which have been successfully undergone, such as the burning fiery furnace in which Shadrach, Meshach and Abednego stood unharmed could probably be explained by reference to natural causes in a similar way, if sufficient evidence were available.

IN a paper on "The Results of some Recent Researches in Electricity," published by the Warrington Literary and Philosophical Society, Mr. J. Reginald Ashworth has presented a summary of the properties of different kinds of rays in the following simple tabular form:—

Name of Ray.	Kathode.	Becquerel.	Röntgen.	Ultra-violet Light.	Red Light.
Existence of Interference, Polarisation, Reflection, Refraction.	o	o	o	×	×
Photographic Effect	×	×	×	×	o
Excite Phosphorescence	×	×	×	×	o
Render Air Conductive	×	×	×	×	o
Penetrate Opaque bodies	×	×	×	o	o
Undergo Deflection by Magnetism	×	×	o	o	o
Velocity relative to that of Light ...	$\frac{1}{7}$	$\frac{1}{2}$	1	1	1

In this table × denotes the existence and o the non-existence of the several properties, and Mr. Ashworth quotes authorities for the statements as to the velocities of the rays.

IN a paper published in the *Verhandlungen* of the Naturforschenden Gesellschaft in Basle, Messrs. Paul and Fritz Sarasin suggest that the low temperature of a glacial period may be due to the obscuration of the sun's rays caused by large quantities of dust-particles suspended in the atmosphere. The phenomena associated with the Krakatoa eruption are discussed, and the widespread effects of this single eruption compared with what may be supposed to have been the result of volcanic activity on the scale known to have prevailed at the end of the Pliocene period.

PROF. W. M. DAVIS contributes a paper to the November number of *La Géographie* on the lessons of the Grand Cañon of Colorado. The conclusions arrived at by the author during a recent visit to this region, and published in the *Bulletin* of the Museum of Comparative Zoology at Harvard College, are used to elucidate its development, beginning with the formation of the *massif* of archæan rock which underlies it, and to show that the cutting of the great gorges is only the last, and by no means the longest, stage of a varied history. Prof. Davis again sets forth his view of the relations between geomorphology and geology, and urges the importance of the former as a branch of geography.

JUDGING from the *Schriften* for 1899, which has just reached us, the Natural History Society of Danzig seems to be in a flourishing condition, the number of papers in the volume before us being very large. Many are of a purely local nature, and some valuable contributions are made to the history of the fauna and flora of the district. Herr E. H. Rübsaämen describes, for instance, the insects and other arthropods obtained during two journeys in the Tuchel forest made in 1896 and 1897; while Herr F. Braun discourses on the ornithology of the Elbing range. Of wider interest is a paper, by Herr E. Treptow, on the progress and results of mining throughout the world during the nineteenth century. An elaborate table of the gold-production of the different countries of the world during the period in question is appended.

IN our last week's issue we noticed two papers from the *Proceedings* of the Philadelphia Academy, of which we had then received only some advance-sheets. The complete current issue (vol. liii. part ii.) has now reached us. Among the more important papers is one by Mr. J. A. G. Rehn on the earwigs, cockroaches, mantids and stick-insects collected by Dr. Donaldson Smith in north-east Africa. Altogether 239 specimens of Orthoptera were collected, of which the grasshoppers, crickets and locusts are reserved for a second paper. A considerable number of species are described as new. The author has also some notes on that remarkable South American bat known as *Centurio senex*, which is regarded as forming a subfamily by itself. In addition to the one on Liu-Kiu Clausilias referred to in our last issue, Mr. Pilsbry has several papers on new molluscs from Japan and the surrounding seas, in the first of which certain Liu-Kiu forms are also described. They are illustrated by several plates. Dr. H. C. Chapman's paper on the placenta and fœtus of the six-banded armadillo is also worthy of note. To ichthyologists Mr. H. W. Fowler's notes on type-specimens of fishes in the Academy's collection will be of interest.

NUMEROUS surveying and drawing instruments—some of a novel character—are mentioned and illustrated in the catalogue just issued by Messrs. W. F. Stanley and Co. Students of branches of engineering, architecture, and other subjects in which exactness of observation and design are required, will find that the catalogue contains many desirable instruments.

IT requires a philosophic spirit to read with patience and profit Mr. Howard Collins's "Epitome of the Synthetic Philosophy of Herbert Spencer." Yet the fifth edition of this summary of Mr. Spencer's completed and revised survey of the universe has now been published by Messrs. Williams and Norgate, thus showing that there are many students who find it of service. Broadly speaking, the book may be described as a collection of abstract propositions, the proofs of which will be found in the ten volumes in which "The Synthetic Philosophy" is elaborated. Mr. Collins manages to give the essence of this work in his volume of nearly 700 pages. "Indeed," remarks Mr. Spencer in a preface, "I have been somewhat surprised that it has proved possible to put so much in so small a space without sacrifice of intelligibility."

THE latest number of the *Proceedings* of the Society for Psychical Research contains 650 pages, in which Prof. J. H. Hyslop gives "A Further Record of Observations of Certain Trance Phenomena," the medium being Mrs. Piper. It need scarcely be said that many of the incidents and results described appear trivial to investigators more familiar with the material sciences than mediumistic performances. A special frame of mind is required even to consider the phenomena patiently.

There seems to be no suspicion of fraud in the case of the phenomena with which Prof. Hyslop is concerned, so that, accepting the observations as records of actual occurrences, an explanation of them is required. The physiologist might be able to throw some light upon them, but he is told that the problem has gone far beyond physiology. "Only the psychologist can any longer deal with the complexities and significance of the Piper phenomena." Telepathy with its necessary adjuncts is also thrown overboard, and spiritism is held to provide a sufficient hypothesis for the data in hand until a better supersedes it. Upon this view there must be a survival of consciousness after death, in a form which is incomprehensible to materialistic philosophers. Prof. Hyslop defines his position as follows:—"I have given a preference for the spiritistic theory in explanation of my alleged facts, in order to force the issue on an important investigation and in order to devolve upon those who have not accepted any supernormal phenomena at all the duty of rescuing me from illusion." Unfortunately, it is not possible for every investigator to study such psychical phenomena as those described by Prof. Hyslop and thus test the value of the observations, so he usually has little interest in them.

Two papers on "La préparation industrielle et les principales applications des Gaz liquéfiés" are contributed by Prof. E. Mathias to the *Revue Générale des Sciences* of October 30 and November 15. Within the limits of twenty-eight pages of a review, much of that space being occupied by illustrations, it is impossible for the author to go deeply enough into the details of the subject to make his papers useful to those who have a fair acquaintance with them, and he does not always give the latest models of apparatus described by him. For general readers, however, the papers form a collection of facts and methods which will give them some insight into an interesting branch of work involving a clearer and closer connection than usual between scientific and industrial pursuits. In the first paper Prof. Mathias gives an account of various processes for liquefying the gases employed in refrigeration. In the second he describes and illustrates a number of machines in which the liquids are employed, and the purposes to which the results are or may be applied. In this connection it is to be regretted that the wild schemes of American company promoters are treated with so much respect, side by side with the descriptions of useful refrigerating machines being a serious account of two companies' automobiles designed to work with liquid air, with an illustration of one of them. The author does not give his readers fair guidance by stating that one of these companies is already in liquidation, and that neither of them has got better practical results than a specially arranged experimental run at a ruinous cost. Those who undertake to instruct the public in these matters with the voice of authority ought to make it clear that liquid air will be far too dear for employment as a source of power until an entirely new method of producing it is invented, and that no such method is as yet even in sight.

A CONSIDERABLE amount of work has been done recently on the ionising properties of liquefied gases, with especial reference to the hypothesis of the connection between the dielectric constant and the dissociating power. An interesting contribution by M. Centnerszwer to this field is contained in the current number of the *Zeitschrift für physikalische Chemie*, in which the conductivity of liquid cyanogen and of anhydrous hydrocyanic acid and of solutions of salts in these is given. In the case of cyanogen, the results of Gore, obtained in 1872, are extended and confirmed. Pure liquid cyanogen was found to have a scarcely measurable conductivity, its solvent power is very slight, and in no case could a proof of dissociation into ions be proved from the conductivity measurements Liquid hydrocyanic acid proved to have a measurable conductivity, which varied, however, in different experiments. Conductivity measurements were successfully carried out with solutions of potassium iodide and trimethylsulphine iodide, with the result that the solutions were found to possess about four times the conductivity of aqueous solutions of the same salts at equal temperatures and concentrations. In connection with the high value of the dielectric constant, these results furnish a new confirmation of the views of Thomson and Nernst on the parallelism between the dielectric constant and dissociating power.

TYCHO BRAHE IN PRAGUE.[1]

THE two papers mentioned below were published by the Bohemian Society of Science on the occasion of the 300th anniversary of Tycho's death. The first one forms a continuation of Prof. Studnicka's "Prager Tychoniana," published about a year ago (NATURE, lxiii. p. 206), and gives the titles of about a dozen volumes from Tycho's library which now belong to the University library at Prague. Several of these volumes contain three or four books bound together, with a few leaves of MS. inserted, among which is a MS. of eight pages (reproduced in facsimile) containing the calculation of the horoscope of Andreas Schoner, who is stated to have been born at Nuremberg on June 21, 1530. This is of interest, not only as showing the various steps of the *modus operandi* of judicial astrology, but also because the date of the younger Schoner's birth has hitherto been unknown (Poggendorff only gives the year 1528). In another volume of mathematical books there is a MS. note to the effect that $\pi = 88 : \sqrt{785}$, which value ($=3·1409$) does not seem to occur elsewhere. On the title page of this memoir is a figure of a medal which Tycho caused to be struck in 1595, probably to commemorate the completion of his star catalogue.

The second paper contains a report on the examination of Tycho Brahe's tomb in the Teyn Church at Prague in June last and on the state of his remains. As it was known that the bodies of some Protestants had been removed from the church after the battle of Prague in 1620 (though nobody has ever alleged that Tycho's tomb had been disturbed), the municipality of Prague allowed the tomb to be opened in order to ascertain whether the great astronomer's bones were still in it. On opening the floor of the church the vault was found to have partly fallen in, so that the two coffins were completely covered with débris and rubbish. We learn from another account (in the journal *Das Weltall*) that this is supposed to have happened in 1679, when part of the roof of the church took fire and fell down after being struck by lightning. The two coffins, which were falling to decay, contained the skeletons of a man and a woman, obviously Tycho and his wife, and slight remains of clothing on the former. Tycho's bones were taken out and put in a box in the vestry until a new metal coffin could be provided, but the writer of the report carried off the front part of Tycho's skull (all that was left of it) in order to examine, measure and clean it, whereby he found that the nose showed distinct signs of having been damaged (in the duel in Tycho's youth), while the green colour of the edges of the injured part no doubt was caused by some composition of copper in the false nose, which in course of time had been completely dissolved. Two illustrations give front and side views of the face, and the account in *Das Weltall* gives pictures of the same before and after the cleaning of the remains. Though we are assured in a footnote that everything was done in a dignified manner, this part of the report is painful to read and reminds one too much of the custom in ancient Brittany, where the inhabitants at the solstices or on the anniversary of the death of a relative took his bones out of the tribal ossuary, scraped them and put them back again. The whole proceeding may possibly have been interesting to an anthropologist (though Tycho did not belong to an extinct or otherwise peculiar race), but we think astronomers will be glad to know that their colleagues at the Prague Observatory had no part in this investigation.

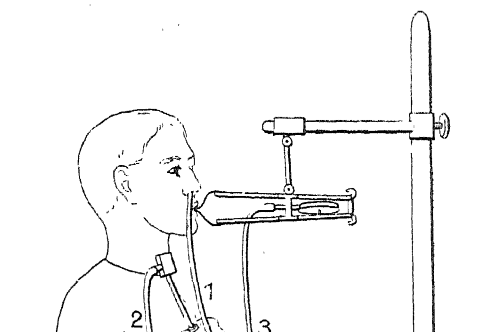
EXPERIMENTAL PHONETICS.[1]

THE movements of the organs of voice and speech are so complicated as to require for their elucidation the application of many methods of research. When one speaks there are movements of the lips, tongue, soft palate and larynx, and sometimes movements of the muscles of expression. Then, again, there are special characteristics about vowel sounds which apparently distinguish these from the sounds of musical instruments. Thus questions arise as to the true nature of vowel-sounds and as to what is the physical constitution of a word of several syllables. It has also been suggested that language might be recorded, not by letters or syllables, but by signs or symbols which would indicate what had to be done by the vocal and articulating organs for the production of any given sound. There might thus be a physiological method of expressing speech by a series of alphabetical symbols for sounds varying in pitch, intensity and quality. It will be seen that experimental phonetics constitutes a wide field of research, not only of great scientific interest, but also one having practical aspects not at first apparent. From the nature of the investigation, also, the problems seem to be specially suited for the application of the graphic method of research.

In 1875, an investigation was carried out by Havet and Rosapelly[2] in the laboratory of Prof. Marey in Paris, in which the pressure of the air in the nose, the movements of the lips, and the vibrations of the larynx were simultaneously recorded. Special contrivances were devised for transmitting these movements to three of Marey's tambours, so arranged as to record on the surface of a blackened drum three superposed curves which indicated the order of succession, duration and intensity of the movements of the organs. The emission of air from the nostril indicated movements of the soft palate, and these were signalled by an indiarubber tube introduced into one nostril while the other end was connected with a tambour, as in Fig. 1. A small electromagnetic apparatus was placed over the larynx, and by making and breaking a current the vibrations of the larynx were transmitted to another tambour. The movements of the lips were recorded by a device which caused the pressures to act on a third tambour, as is shown in the figure.

This method was found to give characteristic tracings for the sounds of consonants, but the records obtained from vowel-sounds were all very much alike. It was also observed that if one of the tambours did not act, say the one recording the vibrations of the larynx, it was difficult to distinguish the tracings of certain consonantal sounds. Thus *p* resembled *b*, so far as the movements of the lips and the nasal pressures were concerned, but with *b* there is a vibration of the larynx as well, while this is absent in the tracing of *p*. In Fig. 2 is shown a table in which is depicted the traces obtained on uttering the vowel *a* either before or after various consonants. In these tracings, P *n* indicates nasal pressure, V *l* vibrations of the larynx, and M *l* movements of the mouth. Five examples are given of combinations of A with consonants. If there is no emission of air from the nostrils, the line P *n* is unbroken and horizontal, but if there is emission then an elevation is seen as in A 3 with *a m*, or *m a*. A sinuous line in V *l* shows that the larynx vibrates, but if there is no laryngeal vibration the line is straight. It will be observed that in some cases the larynx vibrates throughout all the experiment, as in A 2, while in others there is an interruption, as in B 1. The movements of the lips in M *l* show a curve which varies in amplitude and duration according as the lips are more or less approximated and according to the duration of complete or partial occlusion.



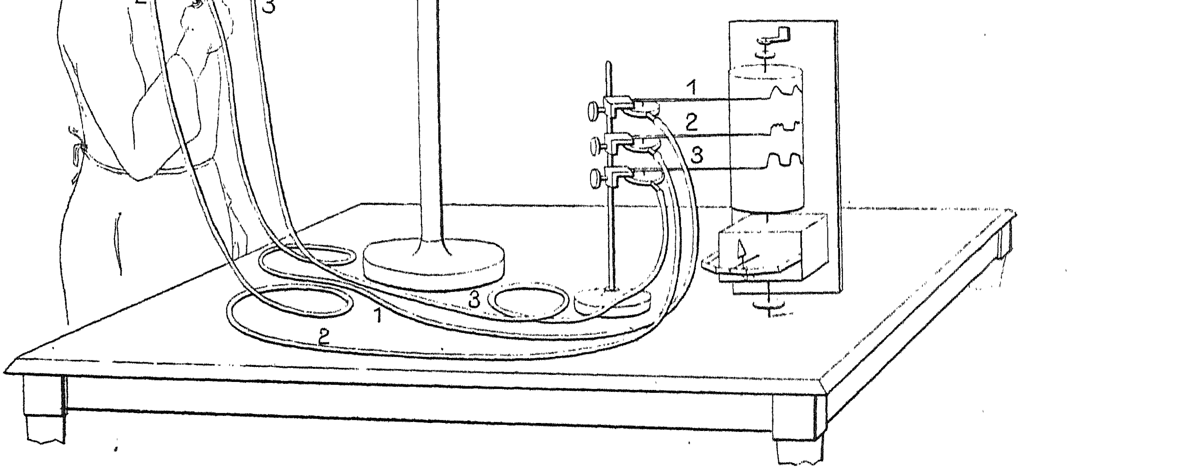


FIG. 1.—A method for recording simultaneously the different acts of speech: emission of air by the nares (tube and lever, 1) vibrations of the larynx (2), and movements of the lips (3).

These syllabic sounds may be termed *phones*. This research is an excellent example of the application of the graphic method to the movements of speech. The method has been much developed by Rousselot[1] in the Collège de France, where there now exists a special laboratory for research in phonetics.

Prof. Marey, whose earlier researches are well known to have had much to do with the development of the kinematograph, employed, so long ago as 1888, chronophotography to catch those evanescent changes of the countenance, the sum total of which give expression to the face in speech. In Fig. 3 are seen the changes of expression in a woman's face in speaking, during a period of half a second. If these successive pictures are projected by a lantern (Fig. 4) there is an animated face on the screen. In this way Marichelle succeeds in placing before the

eyes of deaf mutes images of the movements of speech which they are urged to imitate.

It is interesting, in the next place, to trace the efforts that have been made by physicists and physiologists to record the pressures produced by sound waves and more especially those of the voice. In 1858, Leon Scott invented the phonautograph, seen in Fig. 5. In its first form this instrument gave very imperfect tracings, but it is of great interest as being the forerunner of the phonograph. It was much improved by Rudolph König, of Paris. Donders,[1] in 1868, was the first to use the instrument in the investigation of vowel-tone. Then came the logograph of Barlow[2] in 1876, which was a membrane furnished with a rigid but light lever having its fulcrum at the edge of the membrane while the power was applied from the centre of the membrane. This gave more accurate tracings, that is to say, tracings that indicated with more precision the variations of pressure on the membrane. Examples are given in Figs. 6, 7, and 8.

In Fig. 6 at A the membrane is at rest; at B the lever is raised by the sudden emission of the consonant *b*, and this is succeeded by the prolonged vibration of the vowel *e*. Fig. 7 gives a different picture for *e b*; A is the vowel *e*; B the closure of the lips at the beginning of the consonant; this closure lasts during C, and D is due to the elasticity of the air compressed in the mouth. In Fig. 8, *b e b*, we find the elements of Figs. 6 and 7. By the logograph the consonantal sounds were alone depicted, the records of the vowels being very imperfect.

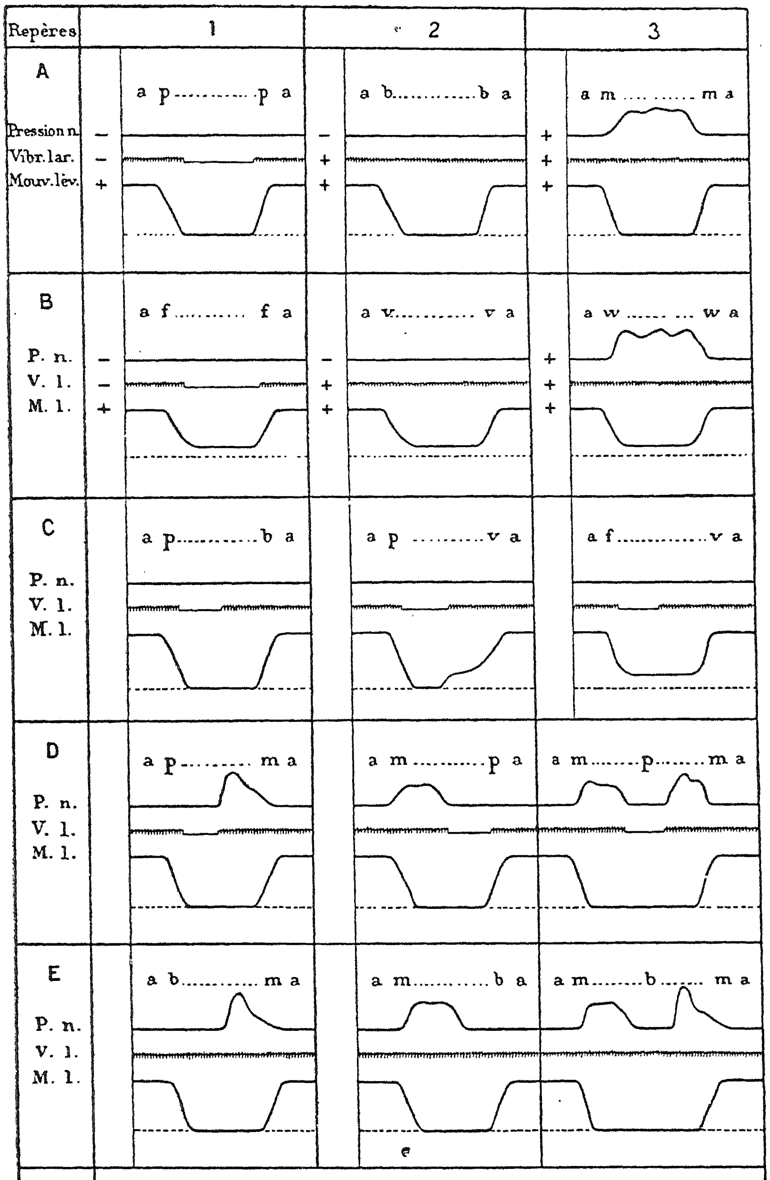

FIG. 2.—Tracings of nasal, laryngeal and labial movements in the pronunciation of various phones.

There was still a demand for a recorder of greater accuracy. Schneebeli,[1] in 1878, devised an instrument seen in Fig. 9. From the centre of a parchment membrane arises a thin but rigid steel plate; attached to this, near the point, is another steel plate passing horizontally from the edge of the metallic ring carrying the membrane. The movements of the membrane are five times increased in amplitude, while the extreme lightness of the lever reduces to a minimum the effects due to inertia. Examples of curves obtained by this method are shown in Fig. 10.

A very sensitive apparatus, termed the *Sprachzeichner*, has also been introduced by Hensen[2] for recording the delicate vibrations of a membrane. It will be readily understood by referring to Figs. 11, 12 and 13. Valuable observations have been made with the aid of this instrument by Wendeler,[3] on consonant sounds, by Martens,[4] on vowels and diphthongs, and by Pipping,[5] on vowels.

Such are some of the mechanical contrivances that have been devised for recording the movements of a membrane. None are free from error, however delicate they may seem to be, owing to the inertia of the parts, and consequently other arrangements were demanded. In 1862[6] Rudolph König introduced his well-known method of showing the movements of membranes by manometric flames. The apparatus is now so well known as to require no detailed description. Gas is led by a tube into a small capsule of wood, the cavity of which is divided by a thin membrane (Fig. 14, A). The gas passes into the right half of the cavity and escapes into a small burner, where it is lit. If sound waves are diverted by a small conical resonator into the left half of the capsule the membranous partition vibrates, there are alternations of compression and of rarefaction in the gas on the right side, and the flame is agitated, moving upwards and downwards with each vibration. The method of Wheatstone of dissociating the flames by a rotating mirror is then employed, and a sinuous ribbon is seen in the mirror. The ribbon is cut vertically into teeth, some larger, some smaller. The larger, less frequent, correspond to the

fundamental tone of the sound, the smaller to the harmonics that enter into the composition of the compound tone on which the quality of the vowel depends.

These flame pictures are only seen for an instant, and many efforts have been made to fix them by photographic methods. This was first attempted by Gerhardt[1] in 1877. He used the flame of cyanogen, and the somewhat poor result is shown in Fig. 16.

Doumer[2] obtained a brilliant flame by burning carburetted hydrogen in oxygen, and he also introduced into such researches a chronophotographic method by reproducing the images of a flame acted on by a tuning-fork of known pitch.

Marage,[1] to whose researches we shall afterwards refer, feeds the capsule with acetylene, and thus obtains a luminous flame. The result of such an arrangement is shown in Fig. 17.

It will be observed that all manometric flames seen in a rotating mirror are inclined, as their composition is due to a horizontal and vertical translation, and the faster the mirror is rotated the more they are inclined.

Efforts have also been made to analyse sounds by photographing a ray of light reflected from a vibrating mirror. Long ago, but without photography, Czermak applied this method to the phenomenon of the pulse, and in 1879 Blake[2] devised a mirror for thus recording speech. He used a small metallic plate, in the centre of which was a small hook which is attached to a very light mirror delicately swung on two pivots, *c*, *c*, Fig. 18.

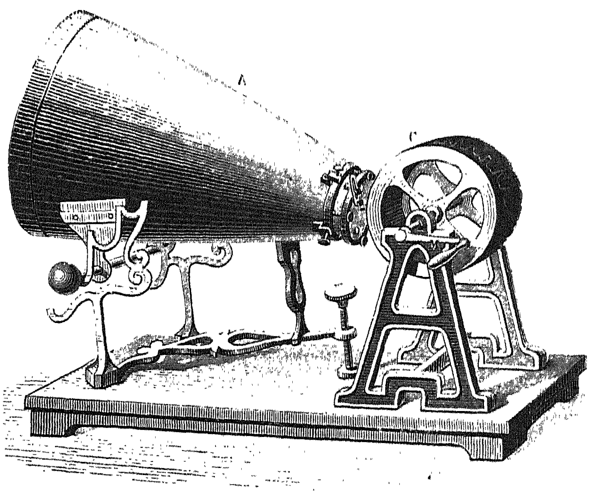

FIG. 5.—Phonautograph of Leon Scott. A paraboloid resonator, closed at one end by a membrane, to which a light lever is attached. C is a drum covered with smoked paper on which the lever traces a curve. As C rotates, it moves from right to left.

A ray of light is thrown on the mirror by a convex lens; after reflection it again traverses a lens and falls on a photographic plate in movement. Sharp, well-defined images are thus obtained (Fig. 19).

The amplitudes of the tracings thus obtained from the tones of the voice were 0^{m}, 025 (1 inch), while those of the mirror were only 0^{mm}, 125 (1/200th inch).

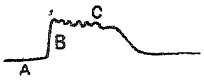

FIG. 6.—Tracings of the sound *b e*.

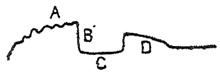

FIG. 7.—The sound *e b*.

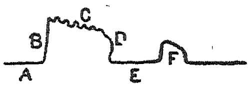

FIG. 8.—The sound *b e b*.

Rigollot and Chavanon,[1] in 1883, constructed a mirror-apparatus shown in Fig. 20, and Hermann,[2] in 1889, used a somewhat similar arrangement, the tracings of which are given in Fig. 21.

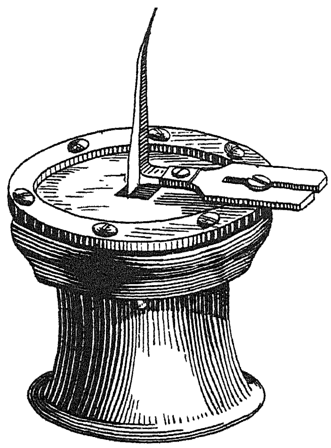

FIG. 9.—Arrangement of Schneebeli for recording movements of a membrane.

An ideal method for recording vibrations was devised by Rops in 1893, ideal inasmuch as it does not use any vibrating membrane or lever, or anything having inertia. A diagram is given in Fig. 22.

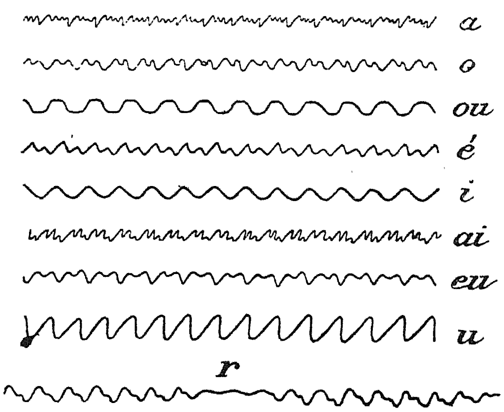

FIG. 10.—Curves of various vowels and of the consonant *r* recorded by the apparatus of Schneebeli.

It is based on the principle of photographing the effects of interferences of light waves. Rays from a luminous source A pass through the lenses *q q* so as to become parallel. They then pass through a slit *d* and a hole in a diaphragm *b*, and they are focussed by a lens *l* (of 15 centimetres focal length) so as to fall on a glass plate S_1. The ray divides into two, a_1 and a_2, and they run parallel, the ray a_1 passing through the air while a_2 passes along a tube *g* (15 centimetres in length), the ends of which are closed by the glass plates *h* and h_1. A few centimetres from the tube there is a resonator, *i*, into which the vowels are sung, thus causing condensations and rarefactions of the air,

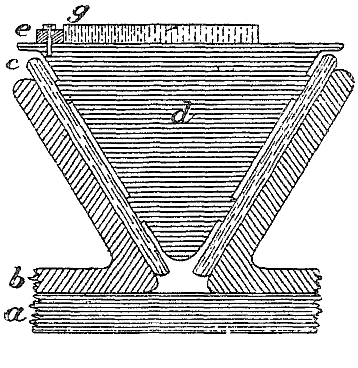

FIG. 11.—Apparatus of Hensen. *d*, Wooden prism; *c*, glass; *g*, smoked glass kept in its place by a screw clamp, *e*; *a*, *b*, supports.

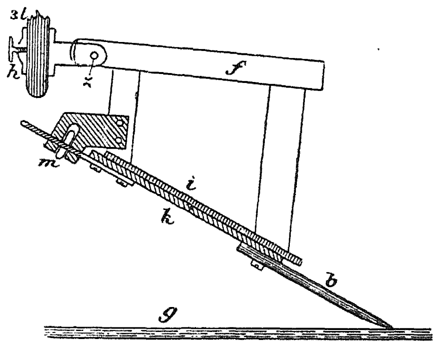

FIG. 12.—The recording portion of the Sprachzeichner of Hensen. *f*, *i*, frame having a joint, *z*; *b*, wooden point; *g*, smoked glass.

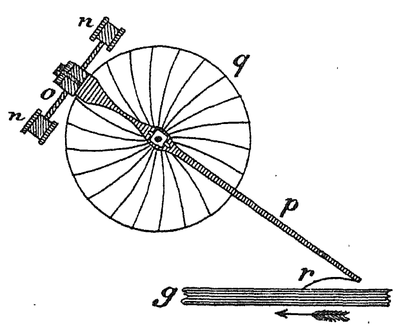

FIG. 13.—Writing portion of Hensen's apparatus. *n*, *n*, weights supporting an axis *o*, carrying marker *p*, with a point *r*; *q*, a disc communicating to the marker *p* the movements of the membrane; *g*, smoked glass plate.

disturbing the ray *h* h_1, while the ray passing through the tube *g* is unaffected. The two rays are again united by S_1; they then pass through an objective *c* and a lens *z* to a slit in a screen so as to fall on sensitive paper on the drum T. A diaphragm *b* cuts off secondary reflections. Thus beautiful images are formed corresponding to the vowels spoken or chanted into the resonator.

The invention of the tinfoil phonograph by Edison in 1877, and the improvement of the instrument by the labours of Edison,

[1] *Journal de Physique*, 1883.

Graham Bell and others in more recent years, has made it possible to investigate phonetic phenomena with the aid of this instrument. In 1878 Fleeming Jenkin and Ewing[1] devised a method of recording curves from the imprints on the tinfoil covering the drum of the phonograph, and these curves were submitted to harmonic analysis. This was also attempted by A. M. Mayer[2] in the same year. The subject was taken up by Hermann[3] about 1890, and he obtained valuable tracings by using the wax-cylinder phonograph. He succeeded in obtaining photographs of the curves on the wax cylinder, a beam of light reflected from a small mirror attached to the vibrating disc of the phonograph being allowed to fall on a sensitive plate while the phonograph was slowly travelling. In 1891 Boeke[4] measured with great accuracy the dimensions of the marks on the wax cylinder, and from these constructed the corresponding curves. This method has also been adopted by Marichelle.[5] McKendrick,[6] in 1895, photographed the marks on the wax cylinder of the phonograph, and in 1896 he devised a recorder for enlarging the curves on the well-known principle of the syphon recorder. In 1899 Scripture,[7] of Yale, investigated vowel-sounds with the aid of the gramophone. He transcribed, by an ingenious mechanical device, the marks on the gramophone disc into the forms of curves, and made a minute analysis. Lastly, Marage,[8] in a series of masterly papers, reinvestigated the whole subject of vowel-tones with the aid of a chronophotographic method and a special form of syren invented by himself.

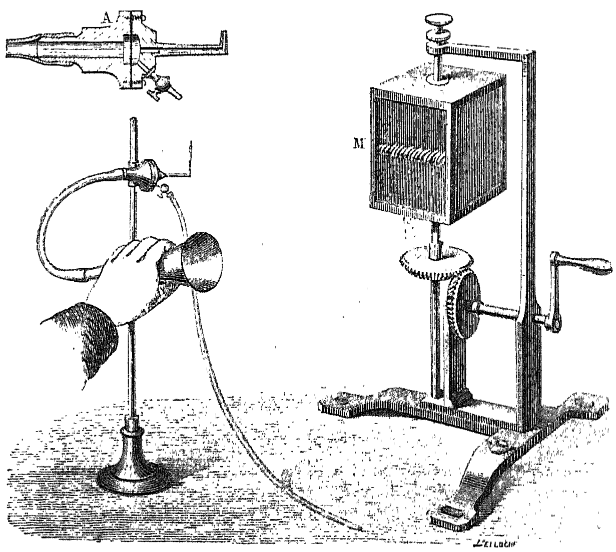

FIG. 14.—König's apparatus. A, Manometric capsule; M, rotating mirror.

The various experimental methods we have described have been chiefly directed to an examination of the nature of vowel-sounds. What is it that gives the peculiar quality to the sound of a vowel? How is it that we can, by the ear, identify the sound of any vowel, whether it be spoken or sung? How is it that if we sing a vowel on the notes of a scale we can still identify the vowel, whatever may be the pitch of the note on which it is sung? The scientific investigation of the nature of vowels begins with Willis,[1] who, in 1829, imitated the larynx by means of a reed, above which he placed a resonator, tuned to one of the harmonics of the reed. He also imitated vowel-tones by holding an elastic spring against the edge of a toothed wheel, and he placed the vowels in the following order—*ou*, *o*, *a*, *e* and *i*. In each case a compound tone was produced which retained the same pitch so long as the wheel revolved at the same rate. By keeping the wheel revolving at a uniform rate, and at the same time changing the length of the spring which was allowed to vibrate, Willis found that the qualities of various vowels were imitated with considerable distinctness. In 1837 Wheatstone,[2] in a criticism of Willis, made some important suggestions. In 1854 Grassmann[3] announced a theory as follows:—The vocal cords excite the resonances of the cavity of the mouth; the tonality changes with the degree of opening of the mouth by the development of some of the harmonics of the fundamental tone emitted by the larynx. According to this view, the buccal cavity adds by its resonance certain harmonics to the fundamental laryngeal sound. Grassmann classified

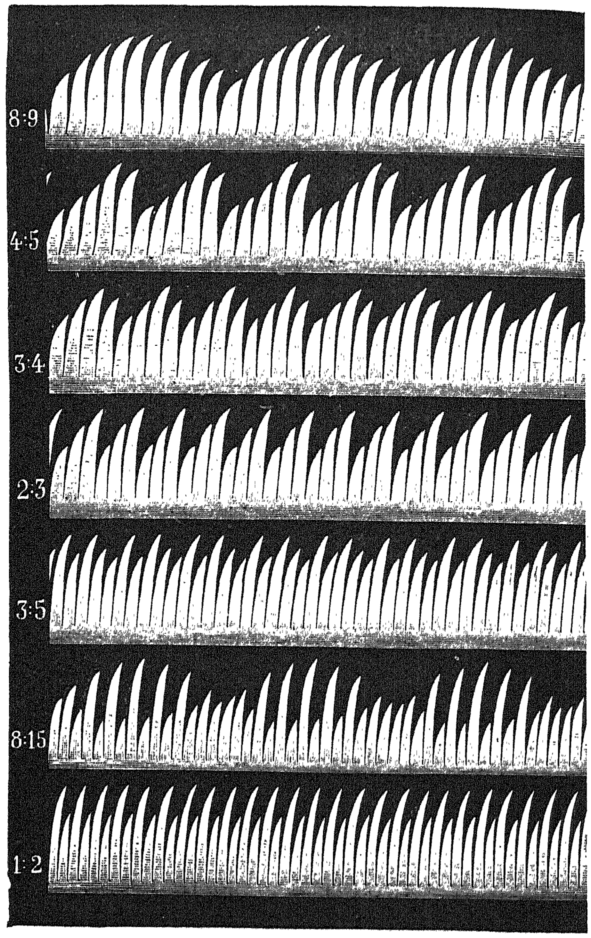

FIG. 15.—Examples of flame-pictures obtained by König's system of a manometric capsule adapted to two organ pipes. The figures to the left indicate the ratio of the vibrations of the two tones forming the compound tone.

the vowels according to the number of harmonics which they contained, in the following table :—

$$a \begin{cases} o \text{ --- } ou \\ eu \text{ --- } u \\ e \text{ --- } i \end{cases}$$

In sounding *a* the mouth is widely opened and the fundamental and eight harmonics are produced; in the third series, on the contrary, there is only one harmonic sounded, which is more and more acute as we pronounce the vowels in the order *ou*, *u* and *i*. The vowels of the second series, *o*, *eu* and *e*, are transitional between the first and the third. Thus we pass from *a* to *ou* by *o*, from *a* to *u* by *eu*, and from *a* to *i* by *e*.

Donders[1] showed that the cavity of the mouth, as arranged for the giving forth of a vowel, was tuned as a resonator for a tone of a certain pitch, and that different pitches coresponded

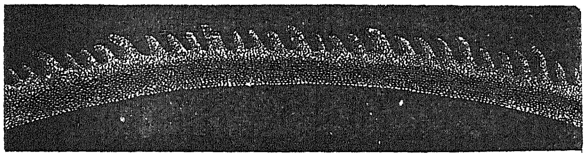

FIG. 16.—Vibrating flame of cyanogen photographed by Gerhardt.

to the forms of the cavity for the different vowels. This he discovered by the peculiar noise produced in the mouth when the different vowels are whispered. The cavity of the mouth is then blown like an organ-pipe and by its resonance reinforces the corresponding partials in the rushing wind-like noise. Then the question was taken up by Helmholtz.[2] He attacked it both by analysis and by synthesis. He analysed the vowel-tones by his well-known resonators, aided by his own singularly acute ear, and he attempted to combine, by means of tuning-forks, the tones which he thought existed in a vowel, so as to reproduce the sound of the vowel. In the latter part of the investigation he was by no means successful. These investigations led Helmholtz to put forward in succession two theories as to the formation of vowels. The first was that, as in all musical instruments, the quality or timbre of the vowel depends on the fundamental tone, reinforced by certain partials or overtones, of which a number are produced by the vocal cords along with the fundamental tone, the reinforcement depending on the resonance of the cavities above the vocal cords. This theory was upset by the use of the phonograph. If a vowel is sung to the phonograph while the cylinder is travelling at a certain speed, the vowel-tone will be reproduced with exactly the same quality if the cylinder is driven at the same speed, but if it is driven faster, then the quality of the vowel will be changed, so much so as to be scarcely recognisable. M. Marey narrates that Donders and he first made this observation when it so happened that the two savants were present in Paris at a public demonstration of the phonograph soon after its invention. Donders sang the vowel tones to the instrument, and then asked the operator to vary the speed of the cylinder during reproduction. Then the vowel *a* became *o*, and *e* became *ou*. Thus while the phonograph reproduces in a wonderful way the tones of musical instruments without change of quality, it cannot transpose vowel-tones without altering their character. This special character or quality cannot, then, depend on the overtones reinforced by the oral cavities being simple multiples of the fundamental tone, and Helmholtz's first theory had to be abandoned.

This led Helmholtz to advance a second theory as follows :— Each vowel is characterised by a certain harmonic or partial tone, of constant pitch, whatever may be the pitch of the note on which the vowel is sung or spoken. Attempts were then made, notably by Helmholtz and König, to fix the pitch of the characteristic partial tone or vocable, and there appeared to be

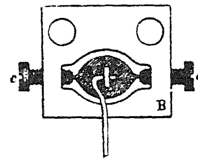

FIG. 18.—Blake's mirror

considerable differences in the results of the two distinguished observers, differences amounting to as much, in some cases, as three semi-tones.

The next step was, as has already been explained, to transcribe the marks on the wax cylinder of the phonograph, made on singing or speaking a vowel, into sinuous curves and to subject these to harmonic analysis. It is not difficult, in comparatively simple cases, to obtain a curve which is the algebraic sum of the ordinates of several sinusoidal curves, but it is not so easy to do the reverse operation, namely, to analyse the curves. Fleeming Jenkin and Ewing, afterwards Schneebeli, Hensen, Pipping and Hermann, have done this in accordance with the theorem of Fourier and the law of Ohm. In particular, Hermann, by a beautiful and ingenious method, has analysed the curves obtained by his photographic device, and has modified the theory of Helmholtz. His statement is that the oral cavity produces independently a harmonic or partial tone which has no definite relation to the fundamental tone emitted by the larynx. A vowel, according to him, is a special acoustic phenomenon, depending on the intermittent production of a special partial, or "formant," or "characteristique." The pitch of the "formant" may vary a little without altering the character of the vowel. For *a*, for example, the "formant" may vary from fa_4 to la_4, even in the same person. He has also attempted, but not with complete success, to reproduce the vowel-tones by synthesis.

There are thus three theories : (1) the first of Helmholtz, now abandoned, that the pitch of the partials is represented by simple multiples of the vibration periods of the fundamental; (2) the second of Helmholtz, that the pitch of the characteristic partial is always fixed, but has a definite relation to the pitch of the fundamental; and (3) that of Hermann, that the pitch

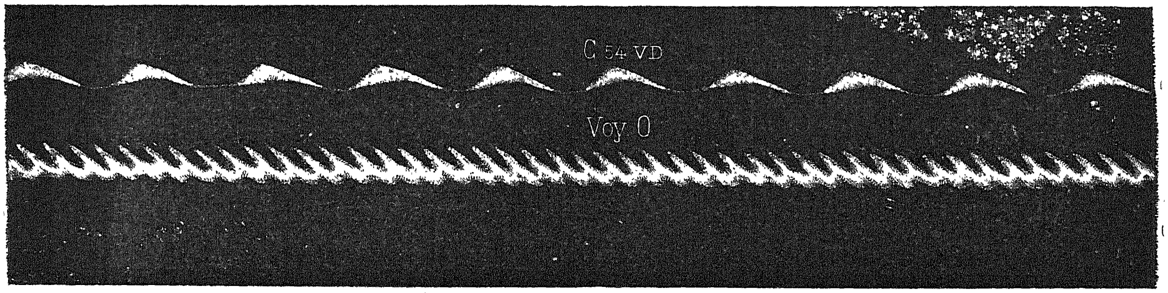

FIG. 17.—Photograph of manometric flames of acetylene showing vibrations of vowel o. Above are the images of chronographic flames—54 double vibrations per second.

of the characteristic partial or "formant" is not absolutely fixed.

The difficulty of harmonising these theories has stimulated the zeal of many workers, and in particular Dr. Marage[1] has been remarkably successful in his researches into the nature of vowels. He first of all criticises the second theory of Helmholtz, pointing out that the failure to reproduce the vowels by synthesis is strongly against it. Thus while, by tuning-forks, the pitch of which is that of the partials of the fundamental tone, *ou*, *o* and *a* may be badly reproduced, it has been found impossible to reproduce E and I. He then objects to the theory of Hermann, namely, that the vowel is an oral intermittent and oscillating tone; first, that the method of recording the vowel on the wax cylinder of the phonograph causes grave errors, because the mouthpiece, tube, air chamber and vibrating disc all profoundly modify the vowel; second, that the method of analysis by Fourier's theorem assumes that the vowel curves are constituted by superposed simple curves, which is precisely the question at issue, and therefore the argument is a *petitio principii*; and third, that the data obtained by his method have

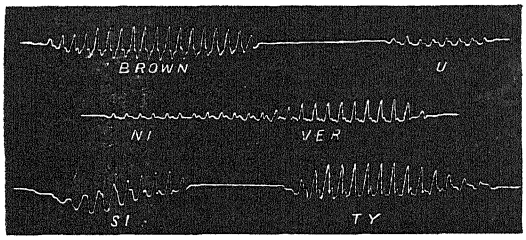

FIG. 19.—Photographic tracings obtained by Blake's method.

not enabled Hermann to reconstruct the vowels with greater success than Helmholtz. Marage then enters upon his own method, which consists essentially of using a special apparatus constructed on König's principle of manometric flames, but so

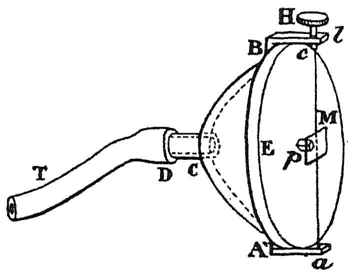

FIG. 20.—Palmoptic capsule of Rigollot and Chavanon (παλμικος, pertaining to vibrations). E F, collodion membrane; M, mirror carried by a wire *a c*, stretched between supports A and B, and regulated by the screw H; *p*, small cube of india-rubber resting on centre of membrane; T, tube.

simple as to be practically free from sources of error; that is to say, there is no mouthpiece, tube or lever. The pictures of the flames were produced photographically by feeding the flame with acetylene gas, and chronophotometrical records were taken with each experiment. He then finds that the flame pictures of I, U and OU show *one* flame, E, EU and O two flames, and A three flames. So that the classification of the vowels by flames is exactly that of Grassmann. Each vowel, when all errors have thus been got rid of by simplifying the apparatus, always gives the same picture for any given note. The picture is that of a continuous periodic curve, and the number of periods in a second corresponds to the laryngeal note, while the *form* of the period characterises the vowel. With the same vowel the period changes with the note. When the note is near the pitch of ordinary speech, the period varies very little. This is not so when the vowel is sung; the period then disappears until there is only the laryngeal note. Marage has also by synthesis reproduced the vowels with remarkable success. His first experiments with resonators were not quite satisfactory; he could reproduce OU, O and A, but not E and I. He ascertained, however, that to reproduce A the resonator must be tuned to the third harmonic or partial of the note on which A was sung; that to reproduce E, EU and O the best result was obtained when the resonator

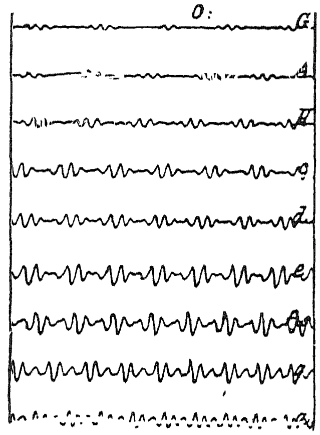

FIG. 21.—Tracings obtained by Hermann of vowel O.

gave the second partial; and I, U and OU were imitated (but not successfully) when the resonator was in unison with the laryngeal tone.

Marage finally devised a syren rotated by an electric motor and consisting of a disc having in it a triangular window representing the glottis. The air is driven under pressure through this aperture and then falls on another disc having windows cut out of it in groups according to the nature of the vowel to be synthetically reproduced. Thus the disc for A has four groups, each group consisting of three triangular slit-like windows; for O and E the disc shows five groups, each consisting of two slits; and for I and OU there are many slits, without these being arranged in groups. The slits are very large for O and narrow for E, and large for OU and narrow for I. He then moulded a series of casts of the interior of the oral and pharyngeal cavities of a human subject, as these were adapted for the singing of the different vowels, and from them constructed masks or head-pieces which could be placed over the syren so that the air escaping from it passed through the cavities of the mask. He found that if air was driven through the masks under a pressure of only 7 centimetres of water, the timbre of the corresponding vowel was at once perceived, as in whispering. Marage's view is that to form a vowel the true vocal cords vibrate in a horizontal plane, in such a way as to influence by their greater or less degree of approximation the escape of air.

If the air escapes in three little puffs as it were (the cords vibrating during each puff a number of times equal to the pitch of the note on which the vowel is spoken or sung), so that

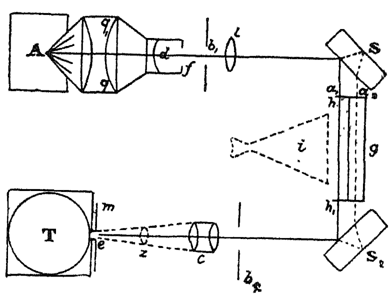

FIG. 22.—Rops' apparatus for the analysis of vowel-tones.

there are intervals between the groups of puffs, then the vowel A is the result. The oral resonator is in unison with the sum of the vibrations and the vowel is emitted. If the resonator (either artificial or the oral cavity, as in life) is turned to the

[1] Marage: "Théorie de la Formation des Voyelles," *op. cit.*

third harmonic of this note, then the vowel A is modified; the same applies to E and O, which have the second harmonic, and in passing from the one vowel to the other it is sufficient to change the aperture of the glottic opening. Thus for A, if the fundamental note is n, the oral resonator must be tuned to $3n$; for E and O, if the fundamental is n', the oral resonator gives $2n'$; and for I and OU the resonator is in unison. If this is not so, then the quality of the vowel is much altered. Thus if the syren gives A, and the plate used is that for OU, then the sound is A modified. This agrees with the experience of teachers of singing, who hold that a badly sung vowel is a vowel-sound emitted into a cavity adjusted for another vowel. Marage has also found that when the sounds of his syren, aided by the masks, are examined by the manometric method, the flame pictures appear as they may be expected to do, that is, groups of three flames for A, of two for E, EU, and O, and of one for I, U and OU. Vowels then, according to him, are due to an intermittent aëro-laryngeal vibration, strengthened by the oral cavity and producing OU, O, A, E and I, when it is in unison with the sum of the vibrations; transformed by it, and giving origin to other vowels, when there is no unison; and the number of intermittences gives the fundamental note on which the vowel is emitted. If the oral cavity acts alone, the vowel is whispered; if the larynx acts alone, the vowel is sung; and if the two act the vowel is spoken. Marage has applied his method with much success in testing the ear and in the treatment of mutes who are not absolutely deaf. His memoir is characterised by great simplicity and at the same time by thoroughness.

But the study of vowels is not the only result of recent research in phonetics. The analysis of consonantal sounds is now being carried out by various workers, such as Pipping, Scripture and Lloyd. Meyer, in Hermann's laboratory, has investigated the pitch of words, sentences and syllables in speech. This has also been studied by phonographic tracings by Marichelle. The whole subject has also a practical bearing, as the knowledge acquired enables the teacher of deaf mutes so to instruct his pupils in the use of their organs as to avoid the dreary monotone of those who learn to speak by watching only the movements of the lips.

It only remains to notice the remarkable monograph of Jespersen. This is an attempt to aid the study of phonetics by the use of a scientific nomenclature to express sounds, so that just as the chemist represents by letters and figures the nature of a chemical substance of complex constitution, so the student of phonetics may be able to express the sounds of words by symbols. The visible-speech system of Melville-Bell consisted of symbols which expressed more or less accurately the physiological movements to be made, or the position to be assumed, during the pronunciation of a given sound; but the symbols of Jespersen are letters and figures. The letters or figures, however, to be useful must have a physiological meaning. Strictly speaking the symbols denote, not sounds, but the elements of sounds. Thus so simple a sound as *m* is physiologically the result of (*a*) lips shut; (*b*) point of tongue resting in the bottom of the mouth; (*c*) surface of tongue not raised towards the palate; (*d*) nasal passage open; (*e*) vocal cords vibrate; and (*f*) air expelled from lungs. The attempt of Jespersen may be called an analphabetic system of writing, symbolising, not sounds, but the elements of sounds. At present it is severely technical, but it seems to "provide a means of writing down and describing phonetic minutiæ in a comparatively easy and unambiguous manner." It will do for the phonetician what symbolism does for the mineralogist. It is a kind of algebra for speech sounds.

In advocating the establishment of a photographic museum, to be a visual register of the past, Janssen recently wrote as follows:—"Photography registers the chain of phenomena during time, just as writing registers the thoughts of men during the ages. Photography is to sight what writing is to thought. If there is any difference, it is to the advantage of photography. Writing is subject to conventionalities from which photography is free; writing employs a particular language, while photography speaks the universal language."

But if there is to be a museum of photographs, appealing to the sense of sight, why should we not have a museum of sounds, in the shape of phonograph records, appealing to the sense of hearing? How little can we tell from written characters the exact sounds of ancient Sanskrit, or how Demosthenes spoke in Greek or Cicero in Latin? Would it not now be interesting to hear the exact accent of old English, or the Scotch of the fifteenth century? All dialects should be carefully registered and put aside for future consultation, and thus we would do for the ear what we do for the eye. No doubt such a collection of phonographic records would help onwards the science of language.

THE ANCIENT GLACIERS OF SKYE.

In the central portion of Skye there is a group of mountains unequalled elsewhere in Britain for rugged grandeur. To the south and south-west lie the Cuillin Hills, the serrated peaks of which rise to an elevation of more than 3000 feet; they are built essentially of a great laccolitic mass of gabbro, traversed by countless dykes and sheets of basalt. To the north lie the Red Hills, the smoother outlines and often ruddy aspect of which contrast markedly with the dark and rough elevations of Blath-bheinn, or Blaven, and the Cuillins; they are composed of granite and granophyre, and rise to heights rarely exceeding 2500 feet.

That the whole of this mountain district has been severely glaciated has for many years been recognised, but the detailed history of the ice-erosion has not hitherto been worked out. Mr. Alfred Harker, in the course of a special survey of the region, has had opportunities of study which have enabled him to write an essay on the subject which for completeness and lucidity is probably unsurpassed.[1] The district, as he points out, is one which had for long been subject to erosion; the drainage system in pre-Glacial times was a fully matured one, and the features then stood out in bold relief. Moreover, the amount of post-Glacial erosion has been so trifling that the effects of ice- and frost-action remain practically without modification by later agencies.

Mr. Harker tells how during the period of maximum glaciation the Skye mountains supported a true ice-cap, under which they were wholly buried, and this ice-cap was sufficiently powerful to withstand and divert northwards and southwards great portions of the ice-sheet from the Scottish mainland. He sees evidence of the movements of the lower layers of ice in the striæ on the rock-surfaces and in the dispersal of boulders; the upper layers not improbably took a course less restricted by the form of the ground. He describes the way in which the ice must have been forced into hollows and openings; its action in grinding down and tearing away rocks, irrespective of their mineralogical composition or structure; and its mode of widening and deepening valleys. Attention is drawn to the formation of cirques or corries, due consideration being given to their aspect and relation to the amount of sunshine. The erosion by ice-action of rock-basins, such as those occupied by Loch Coruisk and other lochs and tarns, is clearly stated and is one of the most effective arguments lately published on the subject.

Mr. Harker's observations lead to the conclusion that the principal glaciation was followed by a later and minor period of ice-action, when glaciers occupied the valleys, and, as would be expected, it is not always possible to discriminate between the work done by the greater and lesser agents. The movement of the later ice was, however, very different on many parts of the lower ground from that during the principal glaciation, a difference due to the withdrawal of the Scottish ice-sheet. To the later glaciation are attributed the perched blocks which occur on the bare slopes of some of the Cuillin valleys. That the higher ridges and summits of the ranges show little or no effects of glaciation is due to the fact that they acted as ice-sheds, and escaped erosion owing to the lack of rock-débris in the ice overlying them.

The mountains, as pointed out by Mr. Harker, are for the most part of bare rock, so also are the higher corries, except where encumbered with screes; while in the lower corries and main valleys the drift is never so thick as to obscure the true form of the ground. Hence the story of the ice-erosion is very plainly engraved on the land, while the author's intimate knowledge of the petrology has enabled him to track the courses of many boulders of peculiar mineral composition with absolute certainty.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE annual meeting of the Association of Technical Institutions will be held at the Skinners' Hall, London, on Friday, January 31, 1902. The Right Hon. Sir William Hart Dyke, M.P., will be in the chair, and an address will be delivered by the president-elect, Lord Avebury.

MR. WALTER PALMER, M.P,, has offered the University of London the sum of 2000*l.* to provide the apparatus required for the proposed post-graduate courses of lectures in physiology. A committee has been appointed to consider the details of the scheme.

THE system of secondary education in Italy forms the subject of criticism at the hands of Prof. Amati Amato, writing in the Lombardy *Rendiconti*, xxxiv. 17. The author regrets that from 1894 to the present time statistical data are very meagre, and it is desirable that a volume should be annually issued showing the number of schools of different grades and their total attendances. The data available for the period up to 1894 are more detailed, and show a marked increase in schools under clerical control and a decrease in those under lay management, and reasons are given for believing that the tendency continues to be in the same direction.

A DEPUTATION representing a number of University colleges waited on the Chancellor of the Exchequer on Friday last in order to place before him reasons why the annual Government grant to these institutions should be increased. In connection with this subject the facts given on p. 175 of this issue are of interest. The grounds upon which the application was made were summarised as follows :—The grant was originally placed upon the Estimates in the year 1889-90, the total amount being 15,000*l.*, apportioned among eleven colleges. An additional grant of 500*l.* was subsequently made to University College, Dundee. In 1897 the grant was increased to 25,000*l.*, which was distributed among twelve colleges. Since then the work of the University colleges has grown in importance and magnitude. New departments have been created, and probably in all the colleges important additions have been made to the teaching staff, together with a largely increased provision of appliances and equipment. In the year 1892 a Treasury committee reported in favour of a total grant of 30,000*l.* being made to the University colleges, a sum in excess by 5000*l.* of that which is at the present time distributed among them. In 1897 new colleges at Reading and Exeter were inspected by a Treasury committee appointed to visit University colleges, and declared at that time not to have reached such a standard in University work as to justify a claim upon a share in the grant. These colleges, together with another, have been again visited by a similar committee, and if by this time they are reported to have reached a standard which justifies their claim to be treated as fully equipped colleges in arts and science some decrease in the grants to other colleges would have to be made unless the total of 25,000*l.* is increased. Replying to the deputation, the Chancellor of the Exchequer said that there was no liability on the part of the Exchequer for University education in England, and declared that this was a doctrine which had always been accepted by Governments and by Parliament. The grant made in 1892 was a purely temporary measure, and did not imply any assumption of liability on the part of the Exchequer. It was only to be regarded as an attempt to aid local effort in places in which there was a strong desire for University education. The experience of the last five years had shown that the grant had had the effect of stimulating local effort. He would carefully consider the whole question; but, while he must decline to pledge himself to any increase of the present grant, he would do his best to prevent any loss falling on the colleges which were now in receipt of it by the admission of new colleges to its benefits.

SCIENTIFIC SERIAL.

American Journal of Science, December.—The geology of the Little Colorado Valley, by Lester F. Ward. The paper is accompanied by a section showing 3500 feet of Trias, of which 1200 are Painted Desert beds, 1600 Shinarump beds, and 700 Moencopie beds.—On pyrite and marcasite, by H. N. Stokes. It is pointed out that although there is no difficulty in distinguishing these two minerals in well-crystallised specimens, there remains a residuum consisting of massive or finely grained material in which this is not possible. The methods which have been proposed for such cases are criticised and found to be insufficient. A method has therefore been developed in which advantage is taken of the difference between the two sulphides in their behaviour towards solutions of ferric ammonia alum, and it has been found possible to apply this to determine the amount of each in mixtures. The application of this process to various samples of doubtful nature, especially of concretions, has shown that the finely fibrous specimens usually passing as marcasite are very commonly pyrite.—Studies of Eocene mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman.—The dielectric constant of paraffin, W. G. Wormwell. Four samples of commercial paraffin were examined with a modified form of the Blondlot oscillator, the refractive index for the D line of the samples being also determined. The dielectric constant of a given paraffin increases with the density of the paraffin. It augments rapidly from a temperature 20° above the melting-point to a temperature 30° below the melting-point, and among different paraffins the dielectric constant increases with a rise in the melting-point. A comparison of the results for short electrical waves and short light waves shows that Cauchy's formula as a means of obtaining the index of refraction for indefinitely long waves does not meet the experimental data.—On some new mineral occurrences in Canada, by G. C. Hoffman.—The estimation of molybdic acid reduced by hydriodic acid, by F. A. Gooch and O. S. Pulman, jun. The conditions under which molybdic acid may be accurately determined by reduction with potassium iodide and hydrochloric acid are here laid down, and test analyses showing the accuracy of the method are cited.—The Veramin meteorite, by H. A. Ward. The meteorite consisted of an intimate mixture of metal and mineral, in roughly equal proportions. Analysis of the metallic portion is given.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 5.—"Notes on Quantitative Spectra of Beryllium." By Prof. W. N. Hartley, D.Sc., F.R.S.

In a quantitative examination made in 1885 of all the known methods of separating beryllium from aluminium and from iron the various precipitates obtained were dissolved and diluted to a known volume corresponding with the amount of bases in solution.

The solutions were spectrographically examined, and the photographs compared with others taken from solutions containing accurately weighed quantities of pure beryllia. Wave-lengths of lines shown by solutions containing 0·000001 per cent. of beryllium : 3322·3 extinct, 3130·3 nearly one-half the line still strong, 2649·8 reduced to a dot, 2493·6 a dot scarcely visible, 2478·1 a very fine short line.

The actual length of the line 2478·1, as rendered by solutions of 0·00001 per cent. and 0·000001 per cent. strength, is, in the former, 0·07, and, in the latter, 0·05 of an inch. The normal length of the line at this part of the spectrum is 0·22 of an inch. The quantity of substance yielding this spectrum is equivalent to one-millionth of a milligramme of beryllium. The coefficient of extinction of the two lines $\lambda\lambda$3130·3 and 2478·1 had not been reached by the dilution specified.

Beryllia has been separated from the alumina contained in felspar obtained from a granite found in co. Wicklow. From numerous experiments on the analytical processes employed in the separation of beryllia from alumina it was found that it remained combined with the sesquioxide bases in so persistent a manner as to lead to the belief that ordinary alumina might be found more often than not to contain traces of beryllia. Such, however, is not the case, though gallium has been ascertained to be present in almost all minerals which contain aluminium. As they belong to the same group, the two elements aluminium and gallium may be expected to form isomorphous mixtures, which would account for their being so constantly associated in nature; but the position of beryllium in the periodic system of classification shows that a similar behaviour with that element is scarcely probable.

Geological Society, December 4.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—On a new genus belonging to the Leperditiadæ, from the Cambrian Shales of Malvern, by Prof. T. T. Groom. Forms referred to Beyrichia have long been known from the Cambrian beds of Scandinavia, Stockingford and South Wales, and the writer has obtained from the

lowest part of the Malvern black shales a species identical with the Stockingford form, which had been provisionally identified with the Swedish *Beyrichia Angelini*. The characters of these specimens serve to separate the species from those now placed under the genus Beyrichia, a conclusion in which Prof. T. Rupert Jones concurs.—The sequence of the Cambrian and associated beds of the Malvern Hills, by Prof. T. T. Groom, with an appendix on the Brachiopoda by Mr. C. A. Matley. The series, exclusive of some 600 feet of igneous rocks, may be estimated at between 2500 and 3000 feet, and consists of the following members, tabulated in descending order:—(4) The bronsil shales, 1000 feet thick; grey shales containing Dictyonema and many Tremadoc brachiopods and trilobites. (3) The white-leaved oak shales; black shales, including: (*b*) The zone of *Peltura scarabaeoides*, *Sphaerophthalmus alatus*, *Ctenopyge pecten*, *Ct. bisulcata* and *Agnostus trisectus*; 500 feet. (*a*) The zone containing *Kutorgina pusilla*, *Protospongia fenestrata*, a new variety of Acrotreta, and a new genus of the Leperditiadæ; 30 feet. (2) The hollybush sandstone, comprising: (*b*) Massive sandstone probably not less than 1000 feet thick, and containing *Kutorgina Phillipsi*, *Orthotheca fistula*, *Scolecoderma antiquissima*, and new species of Hyolithus. (*a*) Flaggy and shaly beds, not less than 75 feet thick; chiefly flaggy and shaly glauconitic sandstones, with *Kutorgina Phillipsi*, *Scolecoderma antiquissima*, *Hyolithus*, &c. (1) The Malvern quartzite, consisting chiefly of grey quartzites and conglomerates, rarely glauconitic; probably at least several hundred feet thick; containing *Kutorgina Phillipsi*, *Hyolithus primævus* and a new species of Obolella. Three new species of Hyolithus are named and described in full, and four in outline, while a revision of Holl's species *H. fistula* is given. Notes are also given, by Mr. Philip Lake and the author, on *Agnostus trisectus*, *Cheirurus Frederici* and other trilobites, and a name is given to certain cylindrical bodies which appear to be the eggs or excreta of some animal.

Entomological Society, December 6.—The Rev. Canon Fowler, president, in the chair.—Mr. J. H. Carpenter exhibited a number of *Colias hyale* bred from ova laid by the parent butterfly taken at Sheerness, August 18, 1900. Twelve months ago there was no trustworthy evidence as to how *C. hyale* passed the winter, but Mr. Carpenter discovered that it hibernates in the larval state and pupates and emerges in the spring. No one has yet successfully bred *C. edusa* through the winter, as they do not, and cannot, feed up these in this country. *Hyale*, on the other hand, is perfectly quiescent during the winter months, and nothing would induce the larvæ to feed at that period even when subjected to a temperature of between 60° and 70° F.—Mr. R. S. Standen exhibited specimens of *Lycaena dolus*, the type, from Bordighera, and also *Pieris brassicae* with greenish underwings, a common form in the neighbourhood of Florence.—Mr. C. P. Pickett exhibited pupa-cases of *Saturnia pavonia*, one with two openings, one with no openings, and a third containing three pupæ, from one only of which the imago had emerged. Mr. J. W. Tutt said that this phenomenon was not unusual in the case of silkworms, and commonly occurred also in the case of artificially bred *Lasiocampa lanestris*, being probably due to overcrowding.—The Rev. A. E. Eaton exhibited specimens of *Psychodidae* of morphological interest, preserved in corked tubes.—Mr. H. St. J. Donisthorpe read a paper entitled "The Life-History of Clythra 4-punctata," and Mr. G. Kirkaldy communicated "A Memoir upon the Rhynchotal Family Capsidæ."

Royal Meteorological Society, December 18.—Mr. W. H. Dines, president, in the chair.—The Hon. Rollo Russell read a paper entitled "Further Observations and Conclusions in relation to Atmospheric Transparency." For a number of years past he had made daily observations on the clearness of the atmosphere at Haslemere, Surrey, and in the paper he gave the results of the same. The principal conclusions derived from these observations are:—Haze and fog are commonly caused by the mixture of currents at different temperatures. These currents may be local or general, high or low. Thick haze or fog not dependent on different currents is rare, but differing currents frequently come into contact without producing haze or fog, and fairly clear weather under opposite currents is not uncommon. A fog may generally be taken *ipso facto* as evidence of the existence in the neighbourhood of a conflict of currents, and prevalent fog or haze commonly signifies that a different wind exists at a high level from that on the surface or at a slight elevation. The production of fog or haze by mixing currents depends chiefly on differences in their temperature. Broadly-extended westerly winds, with westerly upper currents, are the clearest, and visibility may reach the highest figures during their prevalence, whether they are dry or nearly saturated. Easterly and north winds are the most hazy, owing to the ordinary upper current from the west being seldom displaced by them, and to the mixture of these masses of air of different temperatures. When, as an exception, east and north winds are clear, it may be presumed, without direct evidence, that the upper current coincides with them in direction. In winter, therefore, unusual clearness in these winds often signifies a long spell of frost.—The other papers read were: Remarkable phosphorescent phenomenon observed in the Persian Gulf, April 4 and 9, 1901, by Mr. W. S. Hoseason; and the mechanical principle of atmospheric circulation, by Capt. R. A. Edwin, R.N.

Mathematical Society, December 12.—Major MacMahon, R.A., F.R.S., in the chair.—Prof. Love, F.R.S. (hon. sec.) communicated a paper by Mr. J. H. Michell on the flexure of a circular plate. Prof. Lamb, F.R.S., also spoke on the subject of the paper.—Lieut.-Col. Cunningham, R.E., gave a short sketch of Euler's method of finding "amicable" numbers and announced the discovery of two new primes A, B; where $A = f.a$, $B = f.b.b^1$. Then, in one pair, $(A, B) f = 3^4.7.11^2.19$; in the other pair (A, B) $f = 3^5.7^2.13.19$. In both pairs $a = 8747$, $b.b^1 = 53{\cdot}161$.

CAMBRIDGE.

Philosophical Society, November 25.—Dr. J. Larmor, vice-president, in the chair.—The negative radiation from hot platinum, by Mr. O. W. Richardson. The radiation was investigated experimentally chiefly by measuring its variation with the temperature of the metal. The radiating surface was that of a fine platinum wire heated by a steady current. The saturation current from the wire to a surrounding cylinder was measured by means of a sensitive Thomson galvanometer through which the cylinder was put to earth. The pressure in the apparatus varied from ·008 to ·16 mm. The temperature of the wire was obtained by determining its resistance. It was shown that there was no sensible current when the wire was charged positively; with a negative charge on the wire the current rose to as much as 4×10^{-4} amperes at 1600° C. The results are shown to be consistent with the theory that the effect is due to corpuscles escaping from the metal.—On the ions produced by an incandescent platinum, by Prof. J. J. Thomson. The incandescent metal in these experiments was at a temperature between a dull red and a bright yellow heat. At these temperatures only positive ions are produced in the neighbourhood of the wire. Curves showing the relation between the current and the potential difference were obtained; these curves show three well-marked stages. In the first stage the current increases more rapidly than the potential difference. In the second stage the rate of increase of the current diminishes rapidly, the current becoming towards the end of the stage independent of the difference of potential; this at low pressures is followed by a third stage in which the current again increases rapidly, indicating the formation of fresh ions. The currents when the potential difference was increasing differed frequently from those for the corresponding potential when decreasing—the curves often indicating a kind of hysteresis. The saturation current between a hot and a cold platinum plate was found to be independent of the distance between the plates. The masses of the positive ions were determined by the method previously used by the author to determine the masses of the negative ions arising from ultra-violet light or metals at a white heat; it was found that the carriers of electricity were not all of the same kind; the mass of the smallest of these had a mass of the same order as that of a molecule of oxygen.—On the action of incandescent metals in producing electric conductivity in gases, by Mr. J. A. McClelland.—On the seminvariants of systems of binary quantics, the order of each quantic being infinite, by Major P. A. MacMahon.—On the zeros of polynomials, by Mr. J. H. Grace.—The type-specimens of *Lyginodendron oldhamium*, Binney, by E. A. N. Arber.

EDINBURGH.

Royal Society, December 2.—Lord Kelvin, president, in the chair.—The president read an obituary notice of Prof. Tait, which contained interesting reminiscences of their work together when they were preparing "Thomson and Tait."—Dr. Halm, in the second part of his paper, on the state of equilibrium of

stellar atmospheres, gave further illustrations, from the conditions holding in our own atmosphere, of the distinction between thermostatic equilibrium and convective equilibrium, the former being characteristic of the upper strata and the latter of the lower strata, especially in the neighbourhood of mountains. Passing to the case of the sun, he found it necessary to assume (in order to explain the *height* of the chromosphere) that hydrogen gas contains an appreciable amount of potential energy, latent heat, as it were, stored up by the dissociation of its molecules into smaller molecular groups. A comparison of the deviations from Dulong and Petit's well-known law led to a division of the elements into two groups, of which iron and carbon might be taken as the types. In the one group the molecular potential energy increases with the temperature, in the other it diminishes. Hydrogen belongs to the former group. These considerations also gave a clue to the comparative smallness of the layer of metallic vapours in the sun, and, moreover, explained why the spectra of the hottest stars were characterised by a broadening of the hydrogen lines and a narrowing of the lines of the metallic vapours. Finally, it was shown how a change of temperature in part of the sun's photosphere would, on the principles developed in the paper, at once cause violent outbursts of hydrogen gas, such as are observed in the solar protuberances.—Lord Kelvin exhibited a model of the diatomic equilateral crystalline assemblage described in his paper on molecular constitution of matter, Roy. Soc. Edin., July, 1889. By means of this model any relation between the rigidity and the resistance to compression could be obtained, thereby completely disposing of the reasoning of the older French elasticians, who believed that there must be a definite relation between the two elastic constants in an isotropic elastic solid.

DUBLIN.

Royal Irish Academy, December 9.—Prof. R. Atkinson, president, in the chair.—Prof. J. P. O'Reilly read a paper on the waste of the coast of Ireland. In this paper the author discussed the different stages of change that the country had gone through following the work of Prof. Boyd Dawkins, "Early Man in Britain and his Place in the Tertiary Period." Taking the state of the country at the end of the Pleistocene period, when the great forests covered the surface of the upraised drift surface, he pointed out how this has been taken to indicate the then existence of land extending off to the west either as a continental plateau or as a series of islands which sheltered this forest growth, now impossible owing to the harsh winds which come in directly from the ocean. He directed attention to the report of Messrs. Newton and Teall, referred to in NATURE, vol. lvii. p. 324, on the lava sheets of Franz Josef Land, which tends to admit the former existence of an immense basaltic plateau of which the islands Spitsbergen, Jan Mayen, Iceland, Greenland, the Faroes, Hebrides and N. Ireland formed part, the subsequent break-up of this plateau giving rise to islands and to the present state of those mentioned. Explaining how meagre the details are concerning the changes undergone by the coast of Ireland in past times, he pointed out how these might be supplemented by examining what the coasts of the northern islands, Scotland, Cornwall and of France had suffered in loss from the continual beat and wear of the Atlantic storms and waves. The loss and waste he showed to be far greater than is generally imagined, and that Ireland and the islands which once bordered it to the west, south-west and north-west must have undergone, and be actually suffering, very great and serious waste and change. Considering the great scientific importance of the question, it was submitted that it would be becoming on the part of the Royal Irish Academy to promote a survey of the coast line as it actually stands at this commencement of the twentieth century, and to have points fixed as has been done for the coast of Scandinavia, so that hereafter it may be possible accurately to fix the rate at which the island is being wasted away by the Atlantic waves, and in this manner to allow of a determination being made of what was its former extent in prehistoric and early historic times.—Prof. Charles J. Joly read a paper on the point representations of screws. The reciprocal of the quadric in six variables representing screws of a given pitch plus p, taken with respect to the quadric of zero pitch, is shown to be the quadric of pitch minus p. From this property the remarkable relations detailed by Sir Robert Ball in his recent memoir, "Further Developments of the Geometrical Theory of Six Screws," are easily deducible. In the second part of the paper a method is explained of representing a screw by a pair of weighted points in a given plane—the five numbers required consisting of the ratio of the weights and the two coordinates of each point of the pair.

NEW SOUTH WALES.

Royal Society, October 3.—Prof. Liversidge, F.R.S., president, in the chair.—Marriage and descent among the Australian aborigines, by R. H. Mathews. In this short paper the author dealt with the social laws of some tribes in New South Wales, Queensland and elsewhere. Tables and genealogies were supplied illustrating the marriage restrictions, and the descent of the resulting progeny. A brief description was given of certain inaugural ceremonies through which the youths have to graduate in order to reach the status of aboriginal manhood.—On the constituent of peppermint odour occurring in many Eucalyptus oils—part i., by Henry G. Smith. The first Eucalyptus oil was distilled by Dr. White in 1788, at Sydney, and owing to the great resemblance between this oil and that obtained from the peppermint *Mentha piperita*, he named the tree from which he had obtained the oil the "Peppermint Tree." Its botanical name is *Eucalyptus piperita*. Since then many other species of Eucalyptus have been found to have this peppermint odour, and are generally known as "peppermints." The constituent giving this odour has now been isolated. It occurs in greatest amount in the oil obtained from the leaves of *E. dives*, next in that of *E. radiata*, and in fair amount in the oils of several other species. It is usually found in those Eucalyptus oils in which the principal terpene is phellandrene, although this is not always so, but generally there is an almost entire absence of Eucalyptol in those oils in which it occurs most abundantly. The crude oil of *E. dives* was taken for the preparation of this peppermint constituent. This constituent is not menthone, and is probably a new ketone; a molecular determination gave 155, so that probably its formula may eventually be found to be $C_{10}H_{18}O$.—On the crystalline structure of gold nuggets from Klondyke, Victoria and New Zealand, by Prof. Liversidge, F.R.S. Sections of three nuggets from Klondyke were shown. The crystal faces are comparatively small, and the nuggets have a granular structure, as if built up of separate grains, of one or two millimetres in diameter. They are also more fissured and contain more cavities than usual. The sections of Victorian (Australian) and New Zealand nuggets are also made up of small crystals, and they present numerous small cavities after the removal of the quartz and iron oxide by treatment with hydrofluoric and hydrochloric acids, so that the sections present quite a different appearance from the very compact and largely crystallised nuggets from West Australia.

THURSDAY, JANUARY 2, 1902.

THE PHYSIOLOGICAL EFFECTS OF ROUTE MARCHING.

Studien zu einer Physiologie des Marsches. By Dr. Zuntz, Professor of Physiology in the Royal Agricultural College, Berlin, and Dr. Schumburg, Oberstabsarzt 1st Cl. and Privatdocent, Hanover. (Vol. vi. of the *Bibliothek von Coler, Sammlung von Werken aus dem Bereiche der Militär-medicinischen Gebiete.* Edited by O. Scherning.) Pp. viii + 361, and one chart. (Berlin: August Hirschwald, 1901.)

THE "Bibliothek v. Coler" was commenced in March last to celebrate the seventieth anniversary of the birth of Generalstabsarzt Alwin v. Coler, who held the post of Director-General of the Army Medical Service in Germany from the year 1889 until his death in September last. V. Coler was intimately associated with the development of that service ever since its foundation in 1868, and it may truthfully be said that the fine *esprit de corps* which exists in it to-day, and which is characterised by a determination to maintain a high standard of culture and scientific attainment amongst its members, is due to his influence. The collection of works which have been called after him admirably demonstrates what this influence meant. It is edited by Generalarzt Otto Scherning, v. Coler's colleague and ally, and some twenty-six volumes are already announced. They are an excellent expression of the scientific work of the German Military Medical Service, as carried out under v. Coler's guidance and inspiration, as well as of the intimate relationship that exists between army doctors and the teaching professors in Germany.

The authors of the volume under review are well known. Prof. Zuntz's previous work on metabolism is authoritative, and Dr. Schumburg has acquired a wide reputation for original investigations on a variety of military medical subjects. The volume is a record of careful and elaborate observations, made by them, on the physiological effects of route marching. In some of their experiments, notably those involving complicated chemical analyses, they were helped by Prof. Munk, Dr. Nichter, Dr. Frenzel and others.

The introductory chapter is an historical sketch of previous anatomical and physiological work in the same direction from the time of Fabricius de Aquapendente, Gassendi and Borelli to the more modern investigations of Marey, Vierordt, Braune and Fischer. This *résumé* is fairly complete and interesting, but the work done in England is not well represented.

The remaining chapters are an account of the authors' own observations and are of exceptional interest and merit. Five students of the Kaiser-Wilhelm-Academie (formerly known as the Friedrich-Wilhelms-Institut), the cadet school for medical students destined for the military medical service of their country, volunteered for the experiments. During April, May, June and July they marched, at frequent intervals, a distance of 24·75 km. without altering the route or the pace. The marches were commenced, as a rule, at 7 o'clock in the morning, occasionally at 5 o'clock, and two halts were made, one of ten minutes and the other of half an hour for breakfast. The service uniform and accoutrements were worn, and, with the exception of the weather, the only variation in the condition of the marches was in the weights carried. In fact, the experiments were conducted to determine the limit of weight which the soldier can carry without interference with his capacity for striking, and striking hard, at the end of a day's march. Both authors were members of a German War Office committee appointed to decide this point by physiological experiment in 1894, and, although the observations recorded in this volume were conducted during that year, they do not appear to have been made public until now.

It would be difficult in a short review to detail all the points of interest in the volume. They are many. Several of the more important scientific details are contained in tables interspersed throughout the text or brought together in appendices. If the headings of the columns of figures in these tables indicated more precisely what the figures represented, the physiologist would be able to study the records and draw his own conclusions from them without much difficulty. Unfortunately, this is not always the case, and it is often impossible to follow the tabulated records without closely reading the text; and, as is apt to be the case in German works of this kind, the latter is full of argument, comparisons and historical comments which tend to confuse the simple statements of fact. At the same time, it is only fair to say that these interpolations are well-balanced criticisms of the results of the experiments, and that the authors' conception of their own laborious work is dignified and modest in the extreme.

The extent of this work may be estimated from the fact that immediately before and after each march, sometimes during the march and on days of rest, careful examination was made of all the organs and functions of the body that were likely to be influenced by the carrying of a heavily loaded knapsack. This included sphygmographic tracings, enumeration of blood corpuscles, estimation of the specific gravity of the blood, experiments on the reaction of muscles and nerves, measurements of vital capacity and records of variations in urinary constituents. These formed one series of observations only. A second and more complicated series was carried out, in the case of two of the students only, in order to determine the effect of the marches on metabolism, and one must be content to present here a few of the practical results of these investigations without attempting to exemplify the full extent and scope of the work.

After graduated marches with lighter weights, the students were made to carry knapsacks with loads of 22, 27 and 31 kg., and the physiological effects of the lightest, intermediate and heaviest of these loads were compared.

The general condition of the students improved, excessive fat disappeared, while the body-weight was reduced by 1·5 to 3·5 kg. The sphygmographic tracings showed that cardiac systole was prolonged and diastole shortened as the weights carried were increased. This is exemplified by the use of a quotient derived from the formula $\frac{D}{S}$, where D represents the durations of the diastole and S that of the systole in

1/100ths of a second. The mean of the observations made this quotient = 1·73 with a 22 kg. load, 1·58 with 27 kg., and 1·47 with 31 kg., while the lowest quotient of $\frac{D}{S}$ recorded during rest was 1·88 and the highest 3·28. The effect of heavy marches on the systole and diastole of the heart was, therefore, as the authors express it, undoubted. They attribute the result to fatigue of the cardiac muscle and consider that, if the load is raised beyond 31 kg., permanent damage to the heart may result. They also noted that the pulse increased to 140 and 150 beats per minute and that dicrotism became marked as the quotient of $\frac{D}{S}$ approached unity.

Another important and unexpected result was that in a series of eighty-nine observations the cardiac area of dulness showed marked increase in sixty-four and the hepatic area in sixty-seven instances after the march. This increase was noted in 56 per cent. of the observations after a march with 22 kg., in 70·4 per cent. with 27 kg. and in 87·5 per cent. with 31 kg.

Still more important is the observation that the increase in the area of dulness was due to dilatation of the right and not of the left side of the heart, and that it is produced by a general stagnation of the venous circulation. The authors designate the phenomenon "march dilatation of the right side of the heart."

These observations on the cardiac function are new and well worth noting. They have special significance for the military medical officer, as they throw a new light on the condition known as "disordered action of the heart," which is a common sequel of military training and the cause of a considerable amount of invaliding in the British Army.

The observations on other organs and functions did not produce quite such interesting or positive results. The specific gravity of the blood was only increased by ·006 and the red blood corpuscles by 9 per cent. after the heaviest march. An apparent increase of 43 per cent. in the white corpuscles was due to polynuclear cells being carried into the circulation from the walls of the larger veins, in consequence of increased cardiac action; but the blood resumed its normal condition on the day following the march.

The vital capacity of the lungs was studied by means of an experimental gas meter, into which a number of expirations was made in succession, and the volume indicating vital capacity determined by dividing the total record by the number of expirations. This was considered more accurate than records given by Hutchinson's spirometer. Sixty-nine observations were made during marches with loads and eighty-nine during marches without loads. The practical result was that, up to a certain point, the graduated training of the soldier increased his vital capacity, but that a marked diminution occurred in marches with the heaviest loads, this serious result being associated with the dilatation of the heart and liver and the venous stagnation already noted. Another practical observation was that the increase in frequency of respiration, which is invariably associated with exercise, gradually falls to normal during halts, but that when dilatation of the right side of the heart had become well marked, this increase remained as high as 40 per cent. above the normal even after a halt of 30 minutes. The authors conclude that frequency of respiration exceeding 28 per minute, or 75 per cent. increase on the normal, with a gradual fall to 30 per cent. above normal after a quarter of an hour's halt, is the limit which can be borne by a soldier of average strength without breakdown.

The observations on the effect of the marches on body temperature are comparatively brief, but the subject of the regulation of heat and the calorific value of the work done forms a complicated series of calculations and experiments introduced into the chapters which are devoted to the study of metabolism. The authors estimate that the heat production of the work done in marching is sufficient to raise the body temperature 1° C. in 8·7 minutes. In the direct observations there was an actual increase of temperature of 1° to 1°·5 C. only, after the heaviest marches. As the surface cooling resulting from the evaporation of sensible and insensible perspiration plays so important a part in maintaining heat equilibrium, the authors rightly emphasise the importance of attention being paid to the material and nature of the soldiers' clothing with a view to avoiding interference with this function of the skin.

Experiments on the influence of the marches on the nervous system and on muscles were unsatisfactory. Observations were made on the "reaction period," and ergographic tracings were taken with Mosso's apparatus. The results in both cases were inconclusive and conflicting, weather, individual disposition, auto-suggestion, all helping to bring this about. An attempt was also made to estimate the effects of the marches on the nervous system by some ingenious memory tests, but they were so influenced by the drowsiness consequent on the early morning start that the after results were quite inconclusive.

Some interesting facts are recorded in connection with the renal function. Notwithstanding the great loss of water by perspiration, there was no increase in the specific gravity of the urine. Thus the average specific gravity in 150 observations before the march was 1023·6, and after the march 1021·7. This convinced the authors that marching has a diuretic effect, and they recall similar observations by Oertel and Henschen. Their observations on albumin in the urine are also contrary to the general impression, an impression no doubt derived from the observations of Albu and of Macfarlane, that during hard physical exercise transient albuminuria occurs. Zuntz and Schumburg found nothing of the kind amongst their five students, and they point out that Benedicenti had made similar observations on soldiers.

The series of observations and experiments on metabolism includes analysis of nitrogenous waste, respiratory changes, calorific value of the work performed, and the regulation of the body temperature. The observations are of an elaborate and complicated character, and only two of the five students were submitted to experiment. The chief practical results may be briefly noted.

The elimination of nitrogenous products both by the skin and kidneys was not markedly influenced by the marches. When increase did occur, it occurred on the day following the march, and not during or immediately

after the march. The calculation of elimination by the skin was made by careful analysis of the underclothing. The average amount was found to be 284 mg. per litre of perspiration, and as the perspiration increased the proportion of nitrogen eliminated diminished. Thus 2069 grms. of perspiration contained 0·308 per cent. of nitrogen, while 3447 grms. contained only 0·243 per cent. The number of observations on this point was few, and the results suggest the need of further investigation.

In estimating the respiratory changes, the authors made use of the "*tret-werk*," a rolling platform worked by machinery so as to move backwards at the same rate as the individual walking upon it moves forwards. In this manner he remains constantly at the spot where the apparatus for measuring the respired air is fixed. The two students marched on this "*tret-werk*" for six to eight minutes immediately after each march, and for eight to ten minutes during periods of rest, with and without the knapsack. The influence of the marches on the respiratory changes was determined by the "respiratory quotient," *i.e.* the quotient derived by dividing the volume of CO_2 expired by the volume of O inspired. This quotient is equal to unity in the case of herbivorous animals, who obtain their carbon from carbohydrates only and not from hydrocarbons. In carnivorous animals the necessity of using some of the oxygen for the oxidation of the hydrogen in the hydrocarbons, which they consume, diminishes the volume of CO_2 expired in proportion to the oxygen inspired, and the quotient in their case is consequently expressed by a fraction of unity. The authors make use of this fact and show that the "respiratory quotient" is a constantly diminishing fraction after heavy marches. In other words, the carbohydrates are very quickly used up, leaving the fats only as energy-producing material. They conclude from this that, in continuous heavy marching, the carbohydrates consumed in the rations are not sufficient to replace the waste, and that a day's rest is required after every three days' marching to enable the body to recover its normal power.

There are many other points in this volume that are suggestive and of practical importance in military training and in military operations, and it must be regarded as one of the most important works that have been published with reference to several questions that arise in connection with military hygiene. The German military authorities, at any rate, have accepted the conclusions as authoritative, and the regulations bearing upon marching and physical training in Germany are evidently inspired by them.

W. G. M.

LIVES OF THE HUNTED.

The Lives of the Hunted. By Ernest Seton-Thompson. Pp. 360. (London: Nutt, 1901.) Price 6*s*. net.

"LIVES OF THE HUNTED" is practically a second volume to the first of three books noticed in a general review of Mr. Seton-Thompson's work lately published in NATURE (p. 25), "Wild Animals I have Known." When a book has earned a well-deserved success, the temptation to the author to write another on the same lines is strong. But sequels of the kind are seldom as good as the originals, and this is no exception to the rule.

Mr. Thompson is so well up in his subjects that nothing that comes from his pen or pencil can be without interest. The full-page illustrations—more particularly those of the bears in the Yellowstone Park and the big-horn ram facing the wolves—are excellent; but, with some exceptions, neither the letterpress nor the marginal sketches are quite on the level either of the book named above or of the "Biography of a Grizzly."

Unfortunately, too, the little pitted speck noticeable in his earlier writings—more especially in "The Trail of the Sandhill Stag"—a tendency to a rather sickly sentimentality, has grown to disfiguring proportions, and in his last production is a serious blemish.

"The preservation of our wild creatures," to which the book is dedicated, is a worthy object. But it is doubtful whether it is likely to be substantially helped by suggestions, if not actual arguments, which, in spite of Mr. Thompson's assurance that he does "not champion any theory of diet," can only, if pushed to their logical conclusions, mean that mankind is in duty bound to give up eating meat and turn vegetarian. The sneer at "the Saxon understreak of brutish grit, of senseless, pig-dogged pertinacity," which made the old huntsman Scottie stick to the trail of the great ram until the coveted head and horns were his—the race-quality, by the bye, which has helped more, probably, than any other to raise the United States as well as England to the positions they hold among the nations—may appeal, perhaps, to some of his readers, but to others less emotional it may seem a little silly.

"Wolfish human brute" is rather a "brutal" summing-up of the character of the plucky old stalker, whose actual name is given, to come from the pen of a writer who, according to his own account, was not, in trapping days, foolishly over scrupulous.

But when he leaves "gush" and sentiment behind him, and, warming to his work, writes in the bright, unpretentious style which is more natural to him of the things he has seen and known, Mr. Thompson is well worth reading.

"Johnny Bear," the third story in the collection, is a simply-written and charming description of the ways of the bears he studied closely in the Yellowstone Park, and even more delightful, perhaps, is the account he gives of the home and habits of the fairy-like kangaroo rat,

> "the loveliest, daintiest fawn-brown little creature ever seen in fur," with "large beautiful eyes . . . innocent orbs of liquid brown; ears like the thinnest shells of the sea, showing the pink veins . . .; hands the tiniest of the tiny, pinky-white and rounded and dimpled like a baby's."

Sentiment notwithstanding, Mr. Thompson dug out and explored, and in the margin gives a plan of the little creatures' underground establishment, which was safely protected from the attacks of coyottes and other miscreants by the spiked leaves of an overshadowing "Spanish bayonette" bush. It is engineered on much the same general lines as the breeding nest of a mole, with

the addition of granaries for dried seeds—the different sorts kept separately—and with more blind passages. In place of the leaves with which a mole fills its more roughly constructed inner sanctuary, the kangaroo rat's nest was lined with "a thick felting of fine grass and weed silk, and, inside all, a lining of softest feathers." "I think," he writes, "that every gay little bird on the plains must have contributed one of its finest feathers to that nest."

Among the best passages in the book are those in which Mr. Thompson in his first chapter reads the records of the old ram's long life in the gravings of his horns. The deep dent tells of the early battle in which he won his spurs. The two dark-coloured, wrinkled rings close together lower down are reminders of the years of starvation and the sickness which carried off the weaker members of the flock, and the bolder ridges wide apart recall the prosperous years that followed.

He has much to tell that is worth learning, and, left to himself, can tell it excellently. It will be a misfortune to many lovers of natural history besides himself if Mr. Thompson is beguiled into sacrificing himself on the shrine of the admirers who, as he tells in his preface, "bitterly denounced" him for confessing that in unregenerate days he was not above killing a dangerous wolf when he could. T. D. P.

CUBIC AND QUARTIC CURVES.

An Elementary Treatise on Cubic and Quartic Curves. By A. B. Basset, F.R.S. Pp. xvi + 255. (Cambridge: Deighton, Bell and Co., 1901.) Price 10*s.* 6*d.*

NOW that Salmon's "Higher Plane Curves" is out of print there is undoubtedly room for a good book on the subject. The purpose of such a book would be to give students who had read conic sections and the infinitesimal calculus a good knowledge of the main lines on which the theory of curves has been developed. The bookwork would contain discussions of the chief theorems; those of less importance would be given as examples, and would furnish the student with abundant matter for independent thought. The proofs given would, so far as possible, be models of rigour and elegance, and in the rare cases where rigour was sacrificed for the sake of simplicity this would be confessed. The book before us has not been written altogether on these lines. There are no examples, and a great deal of space is taken up in proofs of the properties stated that could, in our opinion, have been put to better use; moreover, the proofs given are not always satisfactory, and even the theorems themselves are sometimes wrongly stated.

After two introductory chapters, chapter iii. deals with tangential coordinates, reciprocal polars and foci, chapter iv. with Plücker's equations. Then we have a chapter on "cubic curves" (pp. 56–73) and another on "special cubics" (pp. 74–96). The special curves discussed are circular cubics, and in particular some that are the inverses of conics, the semicubical and cubical parabolas, the folium of Descartes, the witch of Agnesi. Chapters viii., ix., x. are respectively on "quartic curves" (pp. 101–132), "bicircular quartics" (pp. 133–161), "special quartics" (pp. 162–204). Non-singular, or, as the author prefers to call them, anautotomic quartics, receive attention for three pages only (115, 117, 122). The special quartics discussed are the cassinian, the lemniscates of Bernoulli and Gerono, cartesians, limaçons, the cardioid and the conchoid of Nicomedes. Chapter xi. treats of "miscellaneous curves," roulettes, the evolute of an ellipse, the involute of a circle, the catenary, tractory, elastica and spirals. Chapter xii. is on projection. Some useful references are given in footnotes.

The author has not found space for any general discussion of the forms of cubic and quartic curves, or of the expressions for the coordinates of a variable point on a curve in terms of a parameter, even when the curve is unicursal. The theory of residuation is not mentioned. The following are some of the matters of detail in which the book might be improved.

It is a good thing to "give special prominence to geometrical methods," but we do not think it is sound to estimate, say, the number of tangents that can be drawn from a cusp, real or imaginary, by inspection of the figure (p. 18), especially when no discussion of the form of a curve near a real cusp has been given; the question is in its essence an algebraical one and cannot really be decided except on algebraical grounds.

A process is given (§ 2) for finding the eliminant of two binary quantics of degree n. The result would be of the degree 2^n in the coefficients.

The condition given on p. 4 for the equality of r roots of an equation would lead us to conclude that the equation $3x^4 - 4x^3 + 1 = 0$ has three equal roots.

In the proof of Plücker's equations (chap. iv.) it is only shown that m cannot exceed $n(n-1) - 2\delta - 3\kappa$, and that ι cannot exceed $3n(n-2) - 6\delta - 8\kappa$. It is not proved that the curve and the Hessian meet only at multiple points and points of inflexion.

On p. 62 it is proved that the node of a nodal cubic is a pole of the line of inflexions. The author must have forgotten for the moment that the node is a pole of any line whatever in the plane.

Cayley's theory of conjugate poles on the Hessian of a cubic is treated by means of trilinear coordinates; the figure on p. 70 does not altogether correspond with the text, for it is proved that K lies on the line PQ and that C(AMBK) is a harmonic pencil. Also it is surely wrong to say that when "A is given, there are in general three conjugate poles corresponding to A" (p. 71).

The proof (p. 115) that a quartic cannot have more than eight real points of inflexion is very flimsy; it consists of an appeal to an extreme limiting case.

The assumption that a ternary quartic can be put in the form $lU^2 + mV^2 + nW^2$ is justified by counting the constants (p. 117), although later (p. 240) the reader is very rightly warned "that counting the constants is not always a safe process."

On p. 122 we have the theorem:—

"A conic can be drawn through the eight points of contact of any four double tangents to a quartic." It is well known that this is not true, and it is, in fact, inconsistent with the theorem at the foot of the same page.

There are some other points on which we do not agree with the author, but notwithstanding its drawbacks, the book contains much that is interesting and important.

OUR BOOK SHELF.

Pharmacopedia, a Commentary on the British Pharmacopoeia, 1898. By Edmund White, B.Sc. (London), F.I.C., Pharmaceutist to St. Thomas's Hospital, London, and John Humphrey. Pp. xv+696; 46 plates. (London: Henry Kimpton, 1901.)

THE subject of materia medica is already somewhat unnecessarily complicated in its terminology; the student has to learn the meaning of a formidable array of words before he can even define the subject-matter of his studies. *Inter alia* we may mention pharmacology, pharmacognosy, pharmaco-dynamics, pharmacy, pharmaceutical chemistry, &c. Into this sea of shibboleths the authors of this work have flung yet another which doubtless they hope will float, viz. Pharmacopedia; this in its turn will probably produce Pharmacopedies; by it the authors understand "information about drugs." We venture to think that one of the few mistakes of the book is its title.

The book consists of a full description, either botanical or chemical or both, of all the officinal drugs in the pharmacopœia of 1898, and their preparations. The drugs are treated in alphabetical order, and in this order also the different kinds of preparations are considered generically. The authors have rightly devoted space liberally to the chemical problems involved in the preparation of medicines. They have also discussed at length most of what is known concerning the chemistry of the alkaloids, enlarging this in many cases to a detailed account of the organic chemistry, not only of the substances immediately under consideration, but also those through which their molecular constitution has been ascertained. We may, however, remark parenthetically that we think coniine and digitalis have been treated in this respect a little scantily.

The new synthetic remedies, *e.g.* antipyrin, phenacetine, saccharine, are, so far as their chemistry is concerned, treated very fully, and this will add very greatly to the value of the book. The general remarks upon the oils, methods of standardisation, &c., are also very good and will prove useful to the student.

The book concludes with notes on the Indian and Colonial addendum of 1900 and with numerous well-executed plates of medicinal plants.

The book is well got up, and, as a book of reference like this ought to be, is actually bound, not, as is so often the case, merely enclosed in cloth covers. The authors are distinctly to be congratulated upon the result of their labours and may certainly consider that they have produced the most complete commentary upon the pharmacopœia, from the point of view of the student of pharmaceutical chemistry, in the language. The reviewer would suggest to them that in the next edition they should include once under each drug a brief account of its action and uses, and also its dose. This could be done without appreciably increasing the bulk of the volume and would add immensely to its practical value. F. W. T.

Practical Exercises on Sound, Light and Heat. By J. S. Dexter, B.Sc. Pp. xv + 284. (Longmans, Green and Co., 1901.) Price 2*s.* 6*d.*

THIS book contains elementary exercises, and is of a standard suitable for the work of science and continuation schools and for junior university students. It contains 218 sections dealing with the three subjects, so that the field is covered very completely.

The experiments on heat commence with some to illustrate the sensation of touch used as a thermoscope, and an account, which the student is recommended to take as a guide, is given of the observations. The account begins: "From this lesson I learn that my sensation of touch must not be relied upon to tell me the true heat state of the body I am examining. The thermometer given me to use made no indications of change when placed on different articles, such as wood, iron, or duster, and yet I have different sensations on touching them. . . ." The present writer feels that it would be better for the students, however young, to learn at once the normal English method of recording results and conclusions. He would put the observations first and the conclusion afterwards and avoid the personal pronoun, so that the example for the student would read thus: "A thermometer made no indication of change when placed on the following articles wood, iron or duster, but the sensation to touch was different in each case. . . . From these observations it appears that the sensation of touch cannot be trusted to indicate the heat state of a body."

The methods described by the author for many of the experiments are very simple and satisfactory. We may mention the method of measuring the coefficient of expansion of a rod, and the numerical results show that a good degree of accuracy can be attained. We should, however, have liked to have seen a chapter on the discussion of the value of the errors in the methods. It is not well that students should learn to measure one quantity to five significant figures, another to three and to multiply the two, obtaining a result with eight as we see on p. 47. S. S.

Die heterogenen Gleichgewichte vom Standpunkt der Phasenlehre. Von H. W. Bakhuis Roozeboom. Erstes Heft: Die Phasenlehre—Systeme aus einer Komponente. Pp. xiii + 221. (Braunschweig: Vieweg und Sohn, 1901.)

THIS book will receive a warm welcome from all interested in the phase-rule. Prof. Bakhuis Roozeboom has made the experimental portion of the subject peculiarly his own, and now lays chemists under an obligation of gratitude for a clear and systematic account of Gibbs's rule and its applications. The work is divided into sections according to the number of components in the systems considered, and then further subdivided according to the number of phases in the systems. This method of classification is very advantageous for detailed treatment, especially when many illustrative instances are given, as is here the case. The present section of the book, after a brief general sketch of the nature of the phase-rule, deals with systems containing only one component, the remarkable amount of interesting material collected and classified under this heading showing very strikingly the value of the rule for systematic purposes. Amongst the subjects treated we find the ordinary equilibria of solids, liquids and gases, isomerism, rate of crystallisation, critical points, triple points, transformation points and curves, liquid crystals, enantiotropy—all fully illustrated by examples and with indications of the experimental methods employed. Graphic methods are freely used in the exposition, and only the most elementary acquaintance with mathematics is required for the perusal of the systematic portion of the work. Two other sections are promised, dealing with the equilibrium of systems containing respectively two and three components. J. W.

Knowledge Diary and Scientific Handbook for 1902. Pp. 112+408. (London: *Knowledge* Office.) Price 3*s.* net.

AMATEUR astronomers and other observers of natural phenomena will find it a convenience to possess this diary and handbook. There are, in addition to the 408 blank pages of the diary, several descriptive articles on aspects of astronomy, botany, microscopy and meteorology; star maps; diagrams of paths of the chief planets in 1902; collections of tables of service to students of science; a monthly astronomical ephemeris; and other information of interest.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Kites and Wireless Telegraphy.

IN view of the current report in the daily Press that Mr. Marconi has succeeded in receiving at St. John's, Newfoundland, by means of a wire raised with a kite, signals sent from his station at Poldhu, Cornwall, it may be interesting to recall that kites were used here during the summer of 1899 in some similar experiments. In the "Report of S. P. Langley, Secretary of the Smithsonian Institution, for the Year ending June 30, 1900," it is stated on p. 10: "In addition to the above investigations a Hodgkins grant has been approved to enable Mr. Rotch to carry on a series of experiments in space telegraphy, it being thought that the unprecedented heights attained by kites might materially extend the range of communication by this method. In the preliminary experiments, however, kites were not used, sufficient elevation being attainable without them, but when the difference between the stations was increased from one mile to three, kites were employed to raise the transmitting and receiving wires. In the later experiments it was found, not unexpectedly, that the long wires, carried up and supported by kites, collected so much electricity as to interfere with and greatly complicate the messages sent from station to station. These interruptions seem to show that the limit of elevation for the receiving wire was under these conditions less than five hundred feet. The greatest distance covered in the experiments was approximately twelve miles, from a wire supported by a kite about two hundred feet above Blue Hill to the tower of Memorial Hall in Cambridge, which was used as the receiving station. These experiments draw attention to the fact that electrification increases with the altitude to which the wire is carried, and that it is always present, although varying with the meteorological condition of the atmosphere. The experiments were discontinued in the autumn of 1899."

If Mr. Marconi, by his system, has really received signals from across the Atlantic, with the receiving wire lifted by a kite to an altitude exceeding five hundred feet, it would appear from my experiments that he must have employed some hitherto unknown method of shunting out atmospheric electricity.

Mass, U.S.A., December 17, 1901.

Poisonous Molluscs.

I NOTICE that doubt is cast on the opinion held by some authorities that the bite of certain species of Conus is poisonous; and as a case has now occurred here in a European subject whose intelligence places her account of it beyond question, I think it may be useful to represent the corroborative evidence thus obtained.

I should mention, first, that a shell exactly similar to the one in question was forwarded to the Australian Museum, Sydney, and that I am indebted to Mr. Etheridge, the curator, for information on the point and for the identification of the specimen as the shell of *Conus geographicus*.

The patient, Mrs. B., was fishing from a boat after dark in the harbour of Levuka (Fiji), and one of the crew handed her a mollusc he had picked up in shallow water at low tide while getting bait—a *C. geographicus*. Mrs. B., being an old resident in the islands, proceeded to evulse the mollusc with her little finger, the boy having cracked the shell to facilitate this procedure. While doing so she received a puncture, and shortly afterwards felt her hand and fore-arm becoming numb. The effect quickly extended to the shoulder, and the patient had to return to the shore and be conveyed home. In an hour or so she was in great distress, speechless, and paralysed in most of the voluntary muscles; a condition which later became intensified and alarming, although the cardiac and respiratory muscles showed no evidence of flagging. The medical man who attended Mrs. B. likened her condition to that which might be looked for after poisoning by *curare*.

The puncture was so slight as to be scarcely discernible; after two days a steady but slow recovery took place, and a fatal termination was averted.

During this time the patient did not lose consciousness; but there was for a while some confusion of ideas, and, chiefly in consequence of the loss of power in the muscles concerned in articulation, she was unable to speak intelligibly, although she subsequently asserted that she knew quite well what was going on around her. She underwent an attack of conjunctivitis a few days later, which she connects with the occurrence; but it is doubtful whether she is right or not in so believing.

R. GLANVILL CORNEY.

Medical Department, Fiji, September 30, 1901.

The Distance of Nova Persei.

IT appears to me that the phenomenon of the apparent expansion of the nebula surrounding Nova Persei would be simply explained by referring it to the illumination of meteoric matter by the light sent out on the occasion of the outburst of the Nova. On this hypothesis it becomes possible to calculate the distance from the earth by means of the observed angular growth of the illuminated ring which must spread out with the velocity of light. This gives 313 light-years as the distance.

Daramona. W. E. WILSON.

Colours of Butterflies not due to Diffraction.

SOME time ago your correspondent, Mr. Benham, corrected the mistake that mother-of-pearl owes its beauty to diffracted light. The error had lived long, partly, perhaps, because it came from an authority so eminent as Sir David Brewster.

A similar idea seems to be still prevalent, that butterflies and moths derive their colours from diffraction. Two of the best modern natural histories, which I have at hand, favour the supposition.

The patches on the wing are groups of uniformly coloured scales, which contain pigment. Diffraction colours are of a different character; they are many-coloured iridescent lights varying as they glance off at different angles. The distinction is familiar to a worker in optics; it is easy for anyone to appreciate it by seeing recognised forms of diffraction. I have lately examined a collection of British Lepidoptera, and found no specimens which were coloured by wave interference. The Purple Emperor has two uniform colours, grey and purple, so arranged that there is a direction of vision favourable for seeing each colour. Shot silks and Labrador spar are cases somewhat similar. I have before me a foreign Thecla which has a brilliant light-blue pigment; perhaps in this and some others a certain shimmer is added by a slight diffraction interference, but the predominant effect is the blue colouring matter.

It is, however, interesting to note that all scales have fine diffraction rulings. These lines, as in the case of diatoms, consist of rows of small spots. I have had a wing of the Small Tortoiseshell for about twenty years; the scales are complete, but the colours are faint, and the wing is partly transparent. It is possible to arrange this with care in a strong light so that brilliant rainbow lights are seen, but they are not the familiar tortoiseshell pattern. This effect does not seem to be possible with a fresh wing, so that I doubt whether butterflies are often seen to act as diffraction gratings. No doubt some insects show interference colours, but these seem usually to arise from the phenomenon caused by thin plates. Diffraction can be well studied in humming-birds; there are the brilliant, ever-varying lights, and the fine markings on the feathers may be seen with a microscope. No iridescence is more delicate than that on the side of a fresh mackerel. I am not quite sure to which class of wave interference this is due.

The Quadrantid Meteors.

NOT the least important of our annual star showers are the Quadrantids, so called from the position of their radiant in the constellation of Quadrans Muralis, which is situated between Boötes and Draco. This meteor-system

has not had the same attention lavished on it as has been given to the more historic epochs of the Leonids, Lyrids and Perseids. Yet occasionally, even when only moderately active, the Quadrantid Radiant furnishes displays of about 40 meteors per hour. In the year 1839 Herrick drew attention to the recurring character of a meteor shower on January 2. A stimulus was given in the same direction when in 1839 Quetelet published his valuable contribution to meteoric literature in his "Catalogue des Principales Apparitions d'Etoiles Filantes," in which were cited two instances when meteors were reported to have been unusually numerous on the morning of January 2, viz. in 1835 and 1838. There was also a previous account of the appearance of an extraordinary bolide in the north of Italy in the year 1825, on the morning of January 2 at 5 o'clock, before and after which hour on that night there was noticed a great abundance of meteors.

When Quetelet published a second edition of his work a few years later it contained notices of Quadrantid displays on the same day of the month in the intervening years 1839 and 1840. Their observation in those years, however, may have been due to their having been specially looked for. The next notable display occurred in 1862, and was accidentally witnessed on the morning of January 2, between about 4 and 5 o'clock, by a lady residing in Harford, Connecticut, U.S., who on this occasion seems to have had the honour of being the sole observer of the apparition. Her attention was attracted by a luminous cloud moving from west to east, and also by the appearance of fine meteors at the rate of about three per minute. Two years later there occurred another display in England, on the night, however, instead of the morning of January 2, for which an organised watch had been kept. Profs. Herschel and Gregg (British Association Report, 1864, p. 30) each observed fifty shooting stars from different stations during the hours 10 to 12 p.m. and 10 to 1 respectively, while another observer, Mr. W. H. Wood, reckoned that the Quadrantids were appearing at the rate of one per minute during the hours 12 to 2. Prof Kirkwood, who instituted researches respecting the periodicity of these meteors and also of other meteor-systems, showed in a paper read before the American Philosophical Society in 1873 that the Quadrantid maximum recurred every thirteen years, the principal displays having taken place in 1825, 1838 and 1864. The intervening maximum between the two last dates is supposed, of course, to have passed unnoticed.

The expected shower, however, in 1877 was looked for in vain owing to unfavourable weather, but on the morning of January 2 in the following year, during a brief interval of clear sky beginning at 4 o'clock, Prof. Herschel noted the appearance of seventeen Quadrantids, nearly half of which ranged in brightness from the brilliancy of Sirius to that of second magnitude stars. Weaker apparitions from the Quadrantid radiant also occurred on the nights of January 2 in the years 1872 and 1873, but seem to have been only partially or imperfectly observed. The circumstance that the principal appearances of these meteors evidently took place in 1825, 1838, 1862 and 1864, and (probably) also in 1878 naturally leads to the expectation that another fine display may be observed in 1902. An examination of the dates at which the first three of these showers occurred shows that the Quadrantid meteoric epoch is gradually, as in the case of other well-known star showers, advancing into the year. The advance takes place on the average, however, and is not very noticeable over short periods, being warped by fluctuations in the date of the shower's appearance with respect to the mean date, such fluctuations being produced by the perturbations which occur in the meteoric orbit.

The display in America in the year 1862 and also those on the night of January 2 in 1872 and 1873 illustrate this advance. A calculation made by the writer with such data as the above displays afford shows that the time of the next shower's expected appearance falls on the night of January 4 in 1902, the maximum or centre of the display being due at 3h. 30m. on the morning of the 5th. Earlier in the night, shortly after 12 o'clock, meteors will probably be unusually numerous. The display in 1864 evidently did not attain the brilliancy of the previous displays. Calculation shows that the maximum of this shower occurred about 10 p.m. on the night of January 2, which prevented the shower being fully observed. Probably some early Quadrantids of the expected display will appear on the morning and also early on the night of January 3. The lateness of the maximum on the night of January 4 is more apparent than real, owing to 1900 not being a leap year.

JOHN R. HENRY.

Frost Patterns in Mud.

ON many occasions recently frost patterns in mud have been exceptionally well marked, similar to those formerly described by Prof. Bonney and others (see NATURE, vol. lxiii. p. 347; *Proc.* Roy. Soc, vol. lxiii. p. 217).

On December 15 several of the usual forms were to be seen, the patterns generally being rather coarse, but elaborate, having branched and curving axes.

Thus, (1) on many ordinary flagstones the ice-fronds spread from the centre outwards, over a patch, roughly oval on an oblong stone, roughly circular on a square one, leaving bare a space towards the edge; although sometimes radial or branched forms started from the edge in addition. (2) The centre of the pattern on some flagstones was occupied by a lumpy mass. This consisted of frozen mud, sometimes having a border two to three inches wide formed of scattered separate lumps. (3) One example, however, was rather exceptional. On a concrete path in St. James's Park a space of a few square yards was broken into patches (from a few inches to 2 feet or more in diameter) with outlines roughly hexagonal or partly curved, resembling the ends of basalt columns. In these patches the branching frost-fronds had spread from the centre outwards, while, between the patches, a space about $\frac{1}{3}$ inch broad was clear of ice. This example reminded me of the spheroids with attempts at spherulitic or variolitic structure in various igneous rocks (see *Q.J.G.S.* vol. xlix. p. 155); and here also one asks whether the contraction which caused such jointing was favourable to crystallisation, or did the crystallisation from a centre cause the contraction, or were the two independent though they cooperated to produce the general result?

CATHERINE A. RAISIN.

THE ROYAL COMMISSION ON COAL RESOURCES.

THE announcement that a Royal Commission has been appointed to inquire into the coal resources of the United Kingdom had not been anticipated by public opinion. Yet, in view of the articles on the subject published in NATURE (1897, p. 389, and 1900, p. 124), it should hardly give occasion for surprise. The duration of the British coal supplies is a question that has lost none of its interest since the previous exhaustive inquiry conducted in 1866–1871 by the Royal Commission of which the late Duke of Argyll was chairman. The fifteen Royal Commissioners—all of whom, with one exception, have now passed away—were among the most eminent men of their day, and their calculations were carried out in a thorough and complete manner. In the course of thirty years, however, unexpected changes have taken place in the coal trade. The annual output of coal in the United Kingdom thirty years ago was not more than 100,000,000 tons; it now exceeds 225,000,000 tons, and the process of exhaustion still continues. The beginning of the twentieth century is evidently an opportune time for taking stock of the national resources of the mineral on which so much of the prosperity of the country depends. The new inquiry is to be of a far-reaching character. The terms of reference are as follows: —

To inquire into—(1) The extent and available resources of the coalfields of the United Kingdom; (2) the rate of exhaustion which may be anticipated, having regard to possible economies in use by the substitution of other fuel or the adoption of other kinds of power; (3) the effect of our export of coal on the home supply and the time for which that supply, especially of the more valuable kinds of coal, will probably be available to British consumers, including the Royal Navy, at a cost which would not be detrimental to the general welfare; (4) the possibility of a reduction in that cost by cheaper transport, or by the avoidance of unnecessary waste in working through the adoption of better methods and improved appliances, or through a change in the customary term and provisions of mineral leases; and

(5) whether the mining industry of this country under existing conditions is maintaining its competitive power with the coalfields of other countries.

The chairman of the Commission is the Right Hon. W. L. Jackson, M.P., chairman of the Great Northern Railway Company, and he has fifteen colleagues. Coal-mining interests are represented by Sir W. T. Lewis, the eminent South Wales colliery owner, Sir Lindsay Wood, chairman of the Durham Coal Trade Association, Mr. A. C. Briggs, of Normanton, Yorkshire, Mr. J. S. Dixon, the Scotch coal-master, president of the Institution of Mining Engineers, Mr. A. Sopwith, of Cannock Chase Colliery Company, and Dr. C. Le Neve Foster, F.R.S., professor of mining at the Royal College of Science and Royal School of Mines. The working men's interests are entrusted to Mr. W. Brace, of the South Wales Miners' Federation, and Mr. R. Young, of the Northumberland Miners' Association. Transport interests are in the hands of Sir G. J. Armytage, chairman of the Lancashire and Yorkshire Railway Company, of Mr. Thomas Bell, coal exporter of Newcastle-on-Tyne, and of Mr. J. P. Maclay, shipbroker, of Glasgow. Geology is represented by Mr. J. J. Harris Teall, F.R.S., Director-General of the Geological Survey, by Prof. C. Lapworth, F.R.S., of Birmingham University, and by Dr. E. Hull, F.R.S., formerly Director of the Geological Survey of Ireland, whilst chemistry is represented by Prof. H. B. Dixon. F.R.S., of Owens College, Manchester.

The main interests involved are thus represented with the exception of the consumers. The metallurgical industries, which consume such vast quantities of British coal, do not find their spokesmen on the Commission. This is a matter of regret, inasmuch as metallurgy was so largely represented on the previous Commission; and the investigations of Sir Hussey Vivian, Dr. Percy, Mr. Hartley of Wolverhampton, and Mr. G. T. Clark of Dowlais, on waste in combustion were amongst the most valuable of the results of the Commission.

The task of the Royal Commission to estimate the available resources of the British coalfields is one of great difficulty, and it is to be feared that any estimate must be of slight value, owing to the impossibility of prophesying with accuracy either the rate of increase in production and consumption, or the limits at which mining may be carried on with profit. Prof. Hull, one of the Commissioners, has already published a reassuring estimate, although it is not in accord with the less optimistic and divergent views expressed by Prof. Stanley Jevons, by Mr. Leonard H. Courtney, by Mr. R. Price-Williams and by Mr. T. Forster Brown. The questions of the possible economies in the use of coal and of the adoption of better methods of working should prove the most fruitful field for the Commission's labours. Great Britain now produces one-third of the world's supply of coal; and more and more attention is being devoted to improvements in mining details. Although the use of mechanical coal cutters has by no means become as general as it has in the United States, where 25 per cent. of the output is thus obtained, there has recently been a distinct increase in the use of these labour-saving appliances. Moreover, endeavours are being made to economise in the consumption of coal, notably in the South Staffordshire coalfield, where the producer-gas invented by Dr. Ludwig Mond has recently been introduced as a cheap source of heat and power. That great economies in the home consumption of coal have been effected since 1871 is unquestionable. Indeed, Mr. Price-Williams has shown that, whereas in 1871 the iron and steel trade required 30 per cent. of the coal consumed in the United Kingdom, its requirements had been reduced to 16 per cent. at the time he read his paper before the Statistical Society in 1889. To further coal economies effected in the manufacture of iron and steel Mr. Bennett Brough has drawn attention in an article on the scarcity of coal in the *Nineteenth Century* (April, 1900). There is, however, still room for large economies in coal in the manufacturing industries; and the results of a searching inquiry into the subject cannot fail to be of permanent value and interest.

ON PAPER AND PEROXIDE OF HYDROGEN.

I DESIRE to show by means of the following photographs some special points of interest which occur when certain papers are allowed to produce pictures on a photographic plate in the dark. Some papers are themselves active, that is, if they be simply placed on or near to a photographic plate in the dark they act upon it so that after ordinary development a picture is produced. Other papers which are without this power can be examined by placing them on a photographic plate and putting behind them a plate which is giving off hydrogen peroxide, such as one of plaster of Paris or a pad of blotting-paper which have been soaked in an aqueous solution of this body, or a plate of polished zinc, or a piece of cardboard or glass which has been painted over with copal varnish or other body of that kind. There is also with regard to paper the action of writing and printing ink upon it.

The fibres which are used in paper making are[1] cotton, flax, hemp, wood celluloses, esparto, straw celluloses,

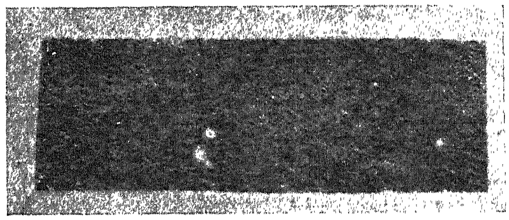

FIG. 1.

mechanical wood pulp. Of these bodies cotton and hemp are entirely without action on a photographic plate; all the other materials are more or less active, especially so is mechanical wood pulp and flax. If, however, any of these bodies, even the most active, be bleached, they lose this activity; the bleaching must, however, be very complete to destroy altogether their activity, and many papers although bleached are still active. On the other hand, the activity of a paper may arise, not from the paper itself, but from the size which has been added; this occurs when rosin is used.

The ordinary first-class papers are entirely without action on a photographic plate, but the common kinds are generally active. For instance, we may take some of the daily newspapers as illustrating this. The following results apply to copies issued on November 25, 1901: the *Standard*, *Daily Express* and *Daily Mail* all gave a dark picture, the *Pall Mall* a good, but not so dark a picture as the former papers; the *Westminster* and the *Sportsman* gave a faint picture, and the *Times*, *Globe* and NATURE only very faint pictures, and, lastly, the *Daily Telegraph*, *Daily News*, *Daily Graphic* and *Morning Leader* gave no picture at all. *Punch* paper is also not active.

With books and periodicals the least expensive are usually the most active; as far as I am aware the paper of high-class books is without action on a photographic plate. Fig. 1 is a picture produced by an active paper.

[1] Report on the Deterioration of Paper, Society of Arts.

This and all the following pictures, when no statement to the contrary is made, have been obtained by an action of the paper on the photographic plate for eighteen hours at a temperature of 55° C. Fig. 2 shows that absolute contact between the active paper and the photographic plate is not necessary, for in this case a thick copper

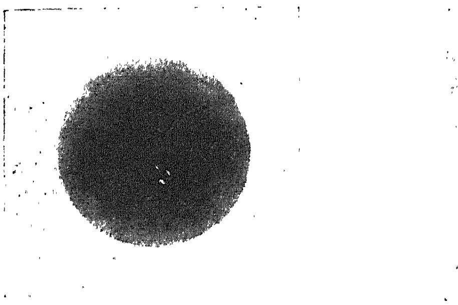

FIG. 2.

screen with a hole in the centre was interposed between the paper and the plate. This action of certain papers is shown in an interesting way with many cardboards. The following experiment, Fig. 3, was made with a photographic mount. A small piece was cut off and on it a long cut was made with a sharp knife passing through the external paper and into the substance of the cardboard. The dark circular patch was where a cork borer had been pressed about half way through the cardboard and the upper part removed. The black ring is a cut made by the same cork borer, but nothing removed. The two dots are two pin holes. Thus it seems as if an active vapour arising from the interior of the cardboard collected in these cavities and acted on the plate. A piece of cork acts in the same way; all the holes give

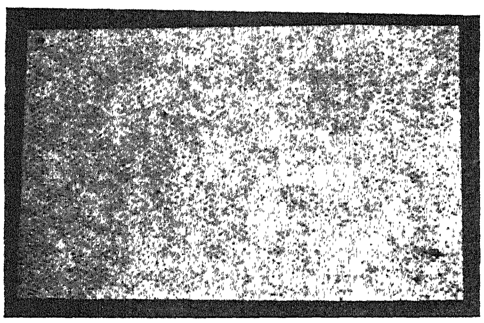

FIG. 4.

black pictures. In this figure the strong action of the recently cut edge is very striking.

Turning now to the case in which the action does not arise from the paper itself, but from hydrogen peroxide purposely placed behind the paper, we can obtain, again, some interesting results. The best way of applying the hydrogen peroxide is by means of a slab of plaster of Paris. This should be cast on a plate of glass and be about a quarter of an inch or slightly more in thickness. After it has been allowed to dry it may be painted over or dipped into a strong or weak solution of the peroxide of hydrogen. The slab is again allowed to dry. It will increase in activity for the first two days and after then gradually decrease, and if a 15 per cent. solution has been used it will be about ten days before it has lost its power of acting on a photographic plate. Other sources of hydrogen peroxide that are convenient to use are a bright zinc plate, or a piece of Bristol board, or a glass plate, that have been painted over with picture copal. Fig. 4 is a picture of the paper of the *Times* produced by placing it on a photographic plate and a charged slab behind it for four minutes. Fig. 5 is the picture of a writing paper 150 years old. The exposure to the hydro-

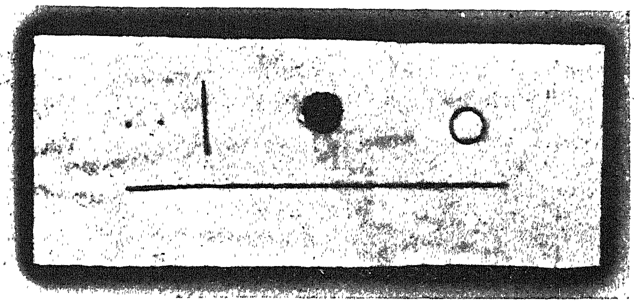

FIG. 3.

gen peroxide in this case was eight minutes, as the paper was thicker and less easily permeated by the peroxide. In the same way it is easy to obtain a good picture of the water-mark on a paper.

This application of the hydrogen peroxide to the back

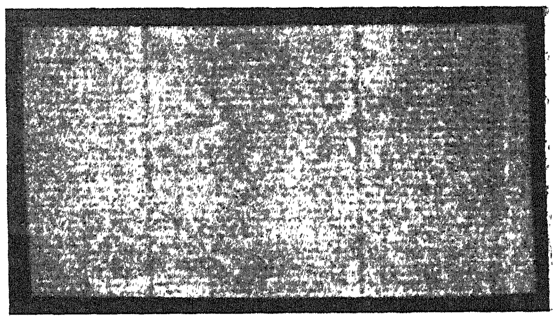

FIG. 5.

of a paper shows an interesting change which paper undergoes on being wetted. Take a paper which is easily permeated by hydrogen peroxide, wet it thoroughly in water, then hang it up at the ordinary temperature until

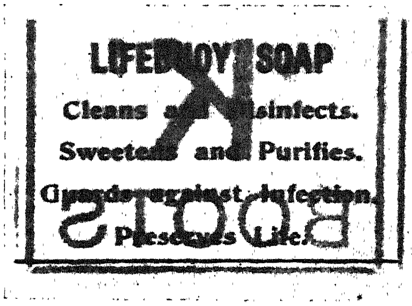

FIG. 6.

perfectly dry, and it will be found to be quite opaque to the hydrogen peroxide given off from a zinc plate or from copal or turpentine. This opacity of the paper, however, gradually passes off, and after two to three days

at an ordinary temperature, or six hours at 100°, it has returned to its transparent state. With Ford blotting-paper the time of recovery is longer. On the other hand, if a paper be made only slightly moist, this facilitates the passage of the peroxide through it. If different substances be dissolved in the water used for wetting the paper it modifies the result obtained. With some substances the paper is not permanently affected, but with others—such, for instance, as alum—the paper remains opaque.

If paper be either written or printed on, the different effects which are produced have been already described.

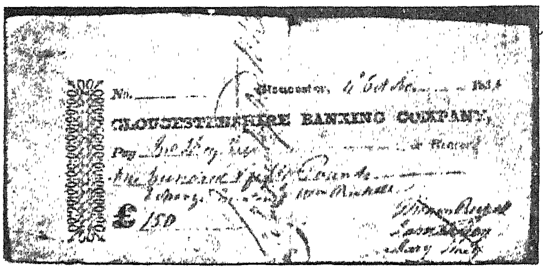

FIG. 7.

The ordinary writing ink, allowed to dry on paper, renders it perfectly opaque to the action of the peroxide and retains this power for a very long time. The direction of a letter written in 1801 shows the writing with remarkable sharpness. The picture was produced by placing a zinc plate behind the letter. Then with regard to printing ink, it is a body which in itself is active, so that it has only to be brought in contact or in proximity to a photographic plate to give a picture. Naturally the activity of the ink varies much in different cases, and is in most cases capable of giving, not only a picture where the ink is facing the plate, but the printing

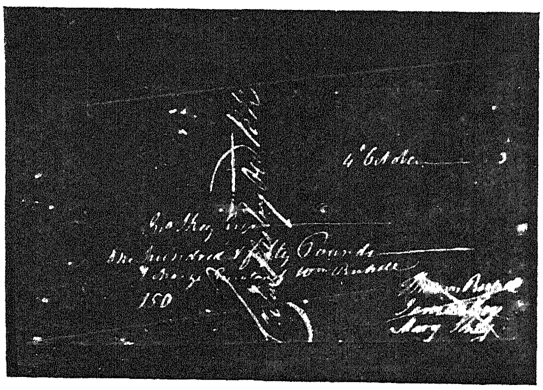

FIG. 8.

on the other side of the paper will also be depicted on the photographic plate. Fig. 6 shows this very well, the printing on both sides of the paper being very evident.

This difference of the action of writing and printing ink is well shown in the two pictures of an old cheque, Figs. 7 and 8. No. 7 is simply an ordinary photograph of the cheque, but No. 8 is a picture of the same cheque produced by placing it on a photographic plate with a zinc plate behind it; the printing-ink has become inactive, but the writing ink is still able to prevent the hydrogen peroxide from passing through.

W. J. RUSSELL.

WHAT ARE SEISMOMETERS INDICATING?

ONE thing which a modern seismometer does, and does in a satisfactory manner, is to indicate the time of arrival of the various phases of motion which constitute an earthquake. With two similar instruments at the same station, the time of commencement of a given earthquake is practically identical; but if the installations of the instruments are different—for example, if the instruments rest upon piers of different heights and construction—it will only be the pronounced phases of the subsequent movements that can be identified and which, therefore, can be compared. If our instruments, instead of being in the same room, are 100 to 800 feet apart, the only points in the two seismograms which can be identified will be the commencements and the pronounced shocks, which latter are of rare occurrence (see British Association Reports, 1885). As a rule not only will the general appearance of the seismograms be different, but measurements will show the existence of differences in period and amplitude. This being the case for seismograms obtained at stations near to each other, what coincidences can we possibly hope for in seismograms obtained at stations located at a few, several hundreds or several thousands of miles from each other?

Next, if we turn to a consideration of the character of the earth movements which produce seismograms relating to earthquakes the origins of which are at a great distance, we meet with observations the explanation of which is not simple. The first rapidly recurring tremors that a seismograph records are regarded as elastic waves of compression and rarefaction. One reason for this belief is that the observed velocities with which these precursors traverse either the surface materials or the body of the earth are such as would be expected for this particular form of wave in the media considered.

Following these forerunners by an interval of time which increases with the distance of the observing station from the earthquake origin are a series of more pronounced movements, usually referred to as shocks or large waves, about the character of which there have been differences of opinion. For earthquakes originating within a few hundred miles of an observing station we find that the records of such waves obtained from bracket seismographs are described as horizontal movements, whilst those from spring-lever seismographs are referred to as vertical components of motion. So long as the latter records are not shown upon a seismogram the former have always been regarded as described, their apparent magnitude being dependent on the multiplication of the writing indices. When, however, in a register we see entries for "vertical motion," neither the measurements for this nor for the corresponding entry for horizontal displacement can be relied upon. The reason for this statement, first made more than ten years ago, is that with severe earthquakes for 100 or more miles round the epicentre we have a vast amount of evidence showing that the ground is thrown into a series of surface-waves. These angular displacements cause horizontal pendulums to swing from side to side, whilst the levers of lever seismographs move up and down, the result being that both types of instruments, instead of measuring components of motion relatively to steady points, act as indifferent clinographs. In consequence of these considerations, at the end of 1891 I designed a clinometer for earthquakes. Briefly, this consisted of a balance-beam loaded at its two extremities, which when its frame was tilted in a direction at right angles to its length was assumed to retain its horizontality. A pointer like that of an ordinary balance attached to this beam acted as a steady fulcrum for the short arm of a light lever, the outer end of which rested on a smoked glass surface. An example of the seismograms giving the period and slope of earthquake-waves obtained by this apparatus will be found in the British Association Reports, 1893.

Inasmuch as these surface-waves could be recognised at a distance of a few hundred miles from their origin, it was naturally assumed that the movements resulting from unusually large disturbances which not unfrequently travel to their antipodes should exhibit the same undulating characteristics. Some support to this view was found in the large movements of delicately adjusted horizontal pendulums, the movements recorded in the traces from magnetographs and barographs, whilst the movements occasionally noted of the bubbles in astronomical levels or the shifting of a star in a telescopic field, together with other phenomena, tended to strengthen the view that the large waves in seismograms represented actual earth tilting. Although I do not yet see how certain of these phenomena can be explained on the assumption of purely horizontal movements, especially when the period of these may exceed twenty seconds, in a British Association Report (September 1900) I published observations indicating that the surface-wave theory met with so many objections that it could not be generally applied. One objection rested upon observations indicating that the velocity of propagation of these waves did not appear to be constant.

Although for certain practical purposes it may be assumed that the arcual velocity of these movements is 3 km. per second, there is evidence to show that they have an initial velocity of about 2 km., whilst their quadrantal velocity approaches 4 km. per second. Dr. C. G. Knott, who has done so much for practical and theoretical seismology, at once pointed out that any change in speed was a serious stumbling-block to the surface-wave theory, which he had always regarded with disfavour. As an alternative, in the *Scottish Geographical Magazine* (January 1899), and in other publications, he showed that the observations relating to speed could be satisfied by the assumption of a distortional mass wave, and it is to the outcrop of such waves to which Dr. Knott looked for the explanation of the large movements of the seismograph.

This hypothesis, however, does not tell us whether the movements actuating a seismograph are vertical, horizontal or angular. Many years ago Dr. A. Cancani pointed out that if these waves represent tilting, from the angular values of the same and the length of the waves which can be deduced from their period and velocity, then on the assumption of simple harmonic motion the height of such waves could be calculated.

Such heights have been frequently estimated, but in the British Association Report (September 1900), p. 83, attention is called to the fact that as these represent accelerations not unfrequently 1/50 of gravity, the existence of these vertical displacements is doubtful, and an experiment to confirm or modify our views was in progress.

The "experiment" referred to consisted in observing the movements of a pointer attached to the earth relatively to the pointer of a clinograph similar to, but much larger than, the one described above. Any relative movement of these pointers would be shown by the displacement of a spot of light reflected from a mirror hung by a bifilar attachment to the two pointers. Subsequently the record was made mechanical. With the first installation 1 mm. deflection =0″·7, and in the second 6″·0. Although several large earthquakes occurred, no record was obtained.

In another experiment slight records were obtained from the photographic registration of a spot of light reflected from a mirror which was caused to rotate by the rising or falling of a weight attached to an ordinary spiral spring. The length of the spring under the influence of its own weight is 9·5 inches. With a load of 1 lb. 8 ozs. its length was 3 feet 5 inches and its natural period 2 seconds.

The earthquake of October 9, 1900, caused ripples on the photogram each about ·5 mm. in range, which would correspond to a change that might have been produced by increasing and decreasing the load by 1/700 part of itself. The period of motion was approximately 6·5 minutes, which corresponded with the period of maxima in the large waves as in an ordinary seismogram.

The Venezuela earthquake of October 29 gave deflections of half the above and with periods of about 7 minutes. Other earthquakes caused somewhat similar movements, but usually nothing more than slight blurs upon the photographic traces were to be seen.

The records from the clinometer indicate that earth tilting has not been measurable by the instrument employed, whilst the records from the spiral spring show that there is a possibility that vertical motion may exist, but if it does it is exceedingly minute.

The general inference is that the large waves due to earthquakes originating at a distance, whether they are surface waves or mass waves, actuate horizontal pendulums by horizontal displacements of the ground, rather than by the tilting of the same.

The distinguished seismologist, Dr. F. Ōmori (see "Publications of the Earthquake Investigation Committee," Tokyo, No. 5, January, 1901), and Dr. Wilhelm Schlütter (see his "Inaugural Dissertation," Göttingen, 1901) have recently expressed similar views. Dr. Omori's objection to the surface-wave theory is based partly upon the impossibility of accepting the vertical accelerations calculated on the assumption that seismographs have acted as clinometers, a view already expressed by Dr. C. G. Knott, Dr. C. Davidson, myself and other physicists, and partly upon the observations he has made showing that the amplitude of seismograms depends upon the multiplication of the writing pointers rather than the sensibilities of seismographs to tilting.

Dr. Schlütter's conclusions are arrived at from the fact that some twenty earthquakes failed to yield any record on the photograms obtained from a "klinograph," which in general arrangement is not unlike those already referred to, but very much more sensitive. The care which Dr. Schlütter took to ensure accuracy can only be realised by reference to his memoir, which, as an essay relating to this class of investigation, stands *facile princeps*.

The general conclusions arrived at are that for severe earthquakes with a near origin, surface earth-waves may be marked. To record these clinographs are required, and the entries in registers referring to the same should be correspondingly modified. In designing instruments to record earthquakes with a distant origin, the principle introduced by Prof. J. A. Ewing into seismometry relating to steady points must be carefully observed, and in our registers we must regard our entries as referring to displacements which are horizontal rather than angular.

J. MILNE.

ELEMENTARY MEDICAL EDUCATION.

WE have received a memorial to the General Medical Council concerning the relegation of the teaching of elementary chemistry, physics and biology to the school, as distinguished from the medical school. The memorial is signed by a number of men of science, teachers of botany, zoology, chemistry or physics. In the opinion of these gentlemen the above subjects should be permanently retained as part of the medical curriculum proper, and their relegation to the schools is, according to them, likely to have a prejudicial influence upon medical education. The most powerful argument, so far as we can see, brought forward in support of this hypothesis is that the schoolboy, as distinguished from the medical student, is intellectually less capable of grasping those scientific generalisations without which the teaching of the elementary scientific subjects above named would not be productive of the desired result, viz. the

development of a truly scientific mind. This as a general statement may perhaps be admitted, though it must be at once pointed out that the difference between the intellectuality of a schoolboy aged sixteen and of a medical student aged seventeen *qua* age is not great, if it exists at all, and postponement of the teaching in these subjects beyond seventeen or eighteen would certainly be impossible.

All are agreed that the attainment of scientific methods of observation and reasoning is a quality of the first importance to the future medical man, especially as the ultimate result of his education, viz. the practice of medicine or surgery, is essentially an inexact science, one in which the data for the formulation of conclusions are extraordinarily inconstant and ephemeral, often demanding for their detection the most trained observation, and for their elucidation the most careful reasoning.

The medical curiculum is, however, filled to the bursting, and unless we want the student to emerge from it partially insane, some depletion must take place. It should also be remembered in this connection that intellectual attainments are not the sole requirements of the medical man. Manipulative skill, and, further, physical training, rendering him capable of enduring physical strain, are also practically essential. This and the fact that the actual subject-matter of medicine and surgery has increased enormously during the last few years, not merely in the direction of biology, chemistry and physics, but also in that of the actual accumulation of clinical fact, render the intellectual burden to be laid, according to the present arrangements, upon the medical student more than he can bear.

Further, the student of medicine stands in a peculiar position with regard to chemistry, biology and physics, for while it is not to be denied that a clear understanding of them is necessary to his education, yet nevertheless it is not only from them that he receives training in the methods of pure science. After having mastered the essential principles of these he still spends two years or more in the study of science, preparatory to entering upon the subject-matter proper of his profession. The first, second, and often third year are devoted to physiology, anatomy and pharmacology; all subjects which tend, not only to store the mind with fact, but also to educate it in scientific method. If the training of the medical student in scientific method depended solely upon the teaching in chemistry, physics and biology, referred to in the memorial we have received, we confess that we should view with concern the relegation of these subjects to the schools; clearly, however, this is not the case, and since something must be done to relieve the overwhelming mass of knowledge to be acquired by the average student in five short years, we feel that the General Medical Council are acting wisely in demanding more of the schools. It is, however, to be hoped that it will see that the school teaching in these subjects is efficient and that the student comes up to the medical school thoroughly grounded in them.

F. W. T.

SUMMARY OF PROGRESS OF THE GEOLOGICAL SURVEY.

THE publication of the Summary of Progress of our British Geological Survey for the year 1900 has evidently been delayed, for we have long ago received and noticed the annual reports of the Canadian and Indian Geological Surveys, and we have likewise referred to the retirement of Sir Archibald Geikie, who in this publication issues his last official report on the work which for so many years he directed. It is a report which, as usual, provides material of sufficient diversity to interest students of all branches of geology. Those who cultivate a knowledge of the oldest rocks will find ample material for consideration in the accounts of the Moine schists and Muscovite-biotite gneiss of Ross-shire, and in the fuller descriptions of the Dalradian or younger schists of the central Scottish Highlands. Thrust-planes and the phenomena of thermo-metamorphism and contact-metamorphism are dealt with, as well as the relations of the schists to the older and newer granites and other igneous rocks. Outside the great granite masses of Lochnagar and the Cairngorm Mountains there is an exceptional extension of cordierite-hornfels, due to the alteration of aluminous black schist; while impure limestones are characterised by the development of silicates, of garnet, idocrase, malacolite and wollastonite. Special attention is drawn to the distinction which it is sought to make between the band of schists known to the surveyors as the "Green beds," originally sedimentary rocks, and the Epidiorites, which occur as sills of much-foliated igneous rock. The "Boulder bed" also forms an important horizon in the mass of Dalradian schists. In some places it affords evidence of having been in part a true conglomerate before any movement such as shearing or crushing took place; elsewhere it appears as a crush conglomerate, or it presents an "augen-structure" on a gigantic scale. In Ireland attention was mainly given to the Silurian rocks of Waterford and Wexford and their associated intrusive and volcanic rocks, which are described in some detail. In the south-west of England work was carried on among the Lower Devonian rocks of Looe in Cornwall and on the various subdivisions of the "Killas" near Falmouth, the "greenstones," and the granite of Penryn.

In the great South Wales coal-field work has been vigorously prosecuted in the district around Swansea. There the Old Red Sandstone and the Lower Carboniferous rocks are of especial interest in connection with their Devonshire equivalents, and it is of the highest interest to learn that radiolarian chert has been recognised in the Gower series described long ago by De la Beche and compared by him with the Coddon Hill beds of North Devon.

The Gower series occurs on top of the main mass of Carboniferous Limestone and belongs to the group of "Upper Limestone shales." These are represented on the north crop of the South Wales coal-basin by "Rottenstone shales," in which also bands of radiolarian chert have been discovered. The upper part of the Gower series consists of a mass of dark shales in which *Goniatites* (*Glyphioceras*) *bilinguis* and *Posidonomya* have been found. At a higher horizon come the hard sandstones and conglomerates of the Millstone Grit. The discovery of these radiolarian cherts is thus an important link in the correlation of the strata in Devonshire and South Wales, for it had been held that the Coddon Hill chert beds might represent the mass of the Carboniferous Limestone. As the work of the Survey proceeds westward further interesting results may be anticipated, especially with regard to comparisons between some of the underlying Lower Carboniferous strata and the Upper Devonian. The Old Red Sandstone has been studied as far north as Caithness, where some of the flags and shales are so bituminous as to become impure oil-shales, while albertite or mineral pitch is found distilled out into the faults and cracks of the strata over large areas. In Argyllshire the relation has been worked out between some of the younger granites of Ben Cruachan, Blackmount and the Moor of Rannoch, and the vents of the Lorne volcanic region. As these vents belong to the time of the Lower Old Red Sandstone, the granites which invade them probably belong to the remarkable series of granite extrusions which in the British Islands intervened between the close of the Upper Silurian and the beginning of the Upper Old Red Sandstone periods.

Details are given of the various coal-seams and of

faults and disturbances observed in the coal-field near Swansea; and important suggestions are made regarding the subdivisions recognised in the Upper Coal-measures of North Staffordshire and their extent westwards across the Cheshire plain, and south-westwards into the Birmingham area.

The discovery of Rhætic, Liassic and Cretaceous fossils in rocks, preserved within an old volcanic vent in the Isle of Arran, is of especial interest as indicating the former extent of these Secondary strata. The Cretaceous rocks of the south of England have received attention, more especially as regards the Lower Greensand of parts of Sussex and the Isle of Wight, the subdivisions in which are compared.

Students of Tertiary strata will find interesting references to the successive overlaps of the London Clay and Bagshot beds on the western side of the Hampshire Basin. The volcanic series of Arran and of Skye come into notice also in the portions of the Summary which deal with Tertiary times.

In various parts of the country observations have been made on Pleistocene deposits, the most important being the full account of the glacial phenomena in the Macclesfield district.

The petrographical work includes a particular account of the marbles of Assynt, which have resulted from contact metamorphism produced by igneous rocks on surrounding dolomites. The palæontological work includes important catalogues of type-specimens of Pleistocene, Pliocene and Devonian fossils preserved in the Museum of Practical Geology; and there are special notes on Carboniferous plants from Berwickshire and on the fossil fishes from the Silurian rocks of the Lesmahagow district. In this brief abstract of some of the results of a year's work on the Geological Survey we have refrained from mentioning individuals, but the work of each has been carefully indicated in the memoir. It is satisfactory, moreover, to note the assistance that has been rendered by Mr. R. Kidston, Dr. R. H. Traquair and Dr. G. J. Hinde in the identification of particular groups of organic remains.

SIR J. HENRY GILBERT, LL.D., F.R.S.

THE names of Lawes and Gilbert have been "household words" in the mouths of English students of agriculture during the past half century. Sir John Lawes departed from amongst us last year, at the age of eighty-five. His colleague, Sir J. H. Gilbert, has also now finished his labours; he died at Harpenden on December 23, at the age of eighty-four.

Joseph Henry Gilbert was the second son of the Rev. Joseph Gilbert, a nonconformist minister at Hull. He was born at Hull in 1817. His mother, Ann Gilbert, was a daughter of the Rev. Isaac Taylor, of Ongar, and thus belonged to a well-known literary family; she was herself the authoress of numerous poems for children. While at school young Gilbert met with a serious accident, and practically lost the sight of one eye. His great pluck enabled him to accomplish his life's work with little apparent hindrance, but the disadvantage of weak sight was very real, and much of his subsequent literary work had to be dictated. He went from school to Glasgow University and studied chemistry under Dr. Thomas Thomson. From thence he went to University College, London, and commenced working in the laboratory of Dr. Antony Todd Thomson. Here apparently he first made the acquaintance of Mr. John Lawes, who was a frequent visitor to the laboratory. He next proceeded to Giessen, where Liebig was then professor of chemistry, and took the degree of Ph.D. in 1840. Dr. Gilbert then acted for a short time as assistant to Dr. Antony Todd Thomson, and afterwards left to take up calico printing and dyeing in the neighbourhood of Manchester.

It was in 1843 that Dr. Gilbert's services were engaged by Mr. Lawes for the agricultural investigations then commencing at Rothamsted. We have already noted in these pages (NATURE, September 13, 1900, p. 467) the foundation of the Rothamsted agricultural investigations by Mr. J. B. Lawes, their rapid development at his sole expense, and their subsequent liberal endowment by him; we have now to mention the important part taken in the work by his collaborator, Dr. Gilbert.

The two investigators were, to a considerable extent, well matched, each supplying some deficiency in the other. Sir John Lawes brought to the work a very original mind, an enterprising spirit, and a thorough knowledge of the facts of practical agriculture; and this practical knowledge served to inform his judgment and enabled him to test the truth of many of the scientific theories which came before him. Sir J. H. Gilbert, on whom the details of the work devolved, brought to his task a more exact knowledge of science and of methods of investigation, an acquaintance with foreign chemists and foreign literature, and, above all, methodical habits of work, which proved of immense value in planning and carrying on through fifty-eight years the field experiments which became such a striking feature in the Rothamsted investigations. He was an indefatigable worker, and loved to accumulate an immense mass of results, frequently of a similar kind; and a reader of Rothamsted papers is sometimes so overwhelmed by numerical statements that, to use a familiar simile, "he finds it difficult to see the wood for the trees."

The Rothamsted investigators soon found themselves engaged in controversy with German men of science, and Sir J. H. Gilbert at once proved himself to be a warm and untiring antagonist. The first subject of dispute was the so-called "mineral theory" of Baron Liebig. Liebig held that the atmosphere supplied in sufficient quantity both the carbon and nitrogen required by crops, and that the proper function of manure was to supply the ash constituents of the crop it was intended to grow. On the other hand, the Rothamsted field experiments with wheat and barley proved unmistakably that ammonium salts and other nitrogenous manures had a far greater effect in increasing the produce than any application of phosphates, potassium salts, or other ash constituents. So long as the question was confined to the cereal crops, Rothamsted was triumphant; but when leguminous crops became the subject of experiment the answer was doubtful, and in many cases the manures supplying ash constituents proved the most effective. It has taken many years, and tasked many investigators, to elucidate this part of the subject. We now know that the roots of leguminous plants become the habitation of certain bacteria, and that by means of these the plants are fed in a special manner with nitrogen from the atmosphere.

The subject of the assimilation of nitrogen by plants led to one of the most highly prized of the Rothamsted investigations, in which plants were grown from seed in soils destitute of nitrogen, but supplied with ash constituents, and in an atmosphere free from ammonia, the object being to ascertain in a rigorous manner if an assimilation of the free nitrogen of the air took place. The work lasted three years, and was made the subject of a communication to the Royal Society by Lawes, Gilbert and Pugh. The chief honour of the work belongs, in this case, to the last-named author. Pugh was an American studying in Germany, and when the controversy on nitrogen assimilation between Boussingault and Ville was at its height he offered to come to Rothamsted and help to solve the question. His offer was accepted. The whole of the experimental work was conducted by Pugh with an ingenuity and accuracy which were justly admired.

In later years another controversy arose as to the part taken by carbohydrates in the formation of animal fat. Lawes and Gilbert had satisfied themselves by their experiments on pigs that fat was undoubtedly produced from carbohydrates. The German physiologists doubted this, and at one time Rothamsted and its followers stood almost alone in their opinion. Now the tide has turned; the experimental evidence for the formation of fat from carbohydrates has become overwhelming, and it is even believed by some that no fat is formed from the albuminoids of the food, but that all the fat stored up by the animal is derived either from carbohydrates or from the fat originally present in the food. The question is one of very great practical importance, the German school formerly insisting that nitrogenous foods must be selected for economic fattening, while the English teaching gave the farmer a much wider choice.

The scope, development and results of the Rothamsted experiments, and the numerous honours jointly conferred on Lawes and Gilbert, have been so recently noticed when speaking of the work accomplished by Sir John Lawes that a repetition of them here seems hardly necessary. Sir J. H. Gilbert was at his death the oldest surviving Fellow of the Chemical Society, having been elected in 1841. He became president of the Society in 1882–3. He was elected a Fellow of the Royal Society in 1860, he served on the Council, and was a regular attendant at the meetings of the Society. With Sir John Lawes he received a Royal medal in 1867. He became a Fellow of the Linnean Society in 1875. He was president of the Chemical Section of the British Association in 1880. He was elected professor of rural economy at Oxford in 1884 and held the office till 1890; the subjects chosen for his lectures were the results of the Rothamsted investigations. He received honorary degrees from several Universities, and was a member of various foreign academies and societies. On the occasion of the jubilee of the Rothamsted experiments in 1893 he was presented with a piece of plate, and afterwards received the honour of knighthood.

Sir J. H. Gilbert carefully maintained through life a connection with foreign workers. His holidays were frequently occupied by visits to scientific meetings and institutions in Germany and France. He made three visits to the United States and Canada, and delivered several lectures there. He enjoyed a very vigorous constitution, and continued actively at work up to the last year of his life. Unfortunately, his disposition forbade his cooperation with any younger colleague, and the institution at Rothamsted is now left without any apparent successor to its historic labours.

The funeral of Sir J. H. Gilbert took place at Harpenden on December 27; deputations from various scientific bodies attended. The Lawes Agricultural Trust was represented by Sir Chas. B. Lawes, Sir John Evans, F.R.S., Mr. W. Carruthers, F.R.S., Prof. H. E. Armstrong, F.R.S., Dr. J. A. Voelcker and Mr. H. Rix; the Board of Agriculture by Mr. T. H. Elliot; the Royal Society by Mr. A. B. Kempe, F.R.S.; the Chemical Society by Prof. W. A. Tilden, F.R.S., and Prof. W. R. Dunstan, F.R.S.; the Linnean Society by Prof. G. B. Howes, F.R.S.; the Meteorological Society by Mr. F. C. Bayard; the Society of Chemical Industry by Mr. A. Smetham.

NOTES.

PROF. W. A. HERDMAN, F.R.S., sailed for Ceylon on December 26, 1901, to undertake for the Government an investigation of the pearl oyster fisheries of the Gulf of Manaar. He is accompanied by a first-rate assistant, and in Ceylon the inspector of the fisheries and his staff will cooperate and provide boats and divers. A suitable steamer for dredging and trawling will be placed at Prof. Herdman's disposal by the Government of Ceylon; and the necessary gear and apparatus for collecting and observational work, and for biological experiments, have been sent out in advance. We understand that Prof. Herdman has arranged to take samples of the plankton throughout the voyage to Ceylon, and to launch current-floats at particular parts of the course.

A PUBLIC meeting was held on Friday last at Cromarty, the birthplace of Hugh Miller, for the purpose of discussing what steps should be taken to celebrate next year the centenary of his birth. Sir Archibald Geikie wrote stating that he heartily sympathised with the object of the meeting and wished all success to the movement which it would initiate. After discussion, a committee was appointed to further a scheme for the erection in Cromarty of a Miller Institute, comprising a library and museum.

IT is proposed to commemorate, on June 15 next, the two hundredth anniversary of the death of G. E. Rumphius, the celebrated naturalist who spent his life in investigation at Amboina, one of the Molucca Islands. The authorities of the Colonial Museum at Haarlem have made arrangements for the preparation of a Rumphius medal, copies of which can be obtained in silver or bronze. Subscribers for the commemorative medals who send their names to the president or secretary of the Haarlem Museum before March 1 will receive a copy of a memorial volume to be published in honour of Rumphius.

THE death is announced of Mr. H. G. Madan, senior Fellow of Queen's College, Oxford, and for twenty years head of the science department at Eton College.

WE learn from *Science* that Mr. Alexander Agassiz, accompanied by Mr. W. McM. Woodworth, has undertaken an expedition to the Maldive Islands in the Indian Ocean, in order to study the coral formations. A steamboat for this purpose has been chartered at Ceylon.

DR. SVEN HEDIN, the Swedish explorer, who recently arrived at Ladakh from Central Asia, has sent a telegram to King Oscar announcing that he has made an extremely important journey through all Tibet, disguised as a pilgrim, with two followers. On approaching Lhasa they were recognised and captured, but were well treated by order of the Dalai Lama. A second attempt was opposed by 500 Tibetan soldiers. Dr. Hedin's collections were lost, with almost the whole caravan, but his notes were saved.

THE Board of Agriculture has appointed a committee to investigate the two diseases of sheep known as "braxy" and "louping-ill." The members of the committee are Prof. Hamilton, of Aberdeen University, Mr. J. McI. McCall, assistant veterinary officer to the Board, Mr. E. J. Wheler, agent to the Duke of Northumberland, with Mr. R. B. Greig, lecturer on agriculture, &c., to the Durham College of Science at Newcastle-on-Tyne, as secretary and demonstrator. The mortality from the diseases in question is a cause of very great loss to the sheep-farming industry in Scotland, probably amounting to between a quarter and half a million of money annually, or even more.

DR. HANS REUSCH, Director of the Geological Survey of Norway, directs attention, in a recent issue of *Naturen*, to the fact that the rock at Moskogaissa mine, 750 m. above the sea, in Lyngen, Arctic Norway, is covered with a frozen moraine from 18 to 20 metres thick. On a previous occasion Dr.

Reusch found permanent ice in a bog near Vadsö. At lower altitudes, where the soil lets the water through, no permanent ice occurs. Still, at Karasjok the ground is not far from a state of permanent freezing. The mean temperature of the place is $-2{\cdot}6°$ C. As it is difficult to dig graves in the ground during winter time, a large hole is made in the autumn and bodies are put into it as people die. The bodies soon freeze hard and sometimes they do not thaw in the spring, when they are buried. It has been found that bodies have remained frozen so long as ten years after their burial.

To the December number of *The Zoologist* Mr. G. Renshaw contributes an interesting article on the extinct blaauwbok (*Hippotragus leucophoeus*) of South Africa. This handsome species, an ally of the sable antelope and the roan antelope, was, it appears, always scarce and local, one of its refuges being the mountains between Swellendam and Algoa Bay, where the last specimens were shot in 1800. Its colour was bluish-grey, with pure white under-parts. The author records sixteen specimens known to have been preserved, but only a few of these appear to be still extant. One skin is now in the museum at Vienna, a second in Stockholm, a third in Upsala, a fourth in Paris and a fifth in Leyden. Our own Natural History Museum possesses a couple of frontlets with horns believed to belong to the blaauwbok. In the same journal Mr. H. E. Howard comments on the marked increase in the numbers of the starling and the hawfinch which has taken place of late years in this country. Writing from Hampshire, he observes of the latter species:—"Fifteen years ago I rarely saw this bird; five years ago small parties of five and six were not at all uncommon; and during the winter now I frequently see as many as a dozen under one yew. This year eight pairs nested within half a mile of my house."

A FEW details concerning the plans of the Scottish Antarctic Expedition are given in the *Dundee Advertiser* of December 25, 1901. The expedition will be directed by Mr. W. S. Bruce, who has had some experience in the Antarctic, and has been engaged in scientific work within the Arctic circle on several occasions. Scientific research will be the chief object of the expedition, and Mr. Bruce will be accompanied by at least seven men of scientific training, who will be engaged with different subjects of investigation. The ship which has been secured for the expedition is a Norwegian whaler called the *Hecla*, a wooden ship of similar dimensions and build to some of the Dundee whalers. The ship will be ready about the beginning of August next and will go for a trial spin for three weeks in the Atlantic for the purpose of testing her gear and instruments before her final departure for the Antarctic, when she will make for the Falkland Islands for the purpose of taking on coal and provisions, and then strike for the field of operations in the Weddell Sea—a region of the Antarctic about which nothing is known, and which has only once been visited by an exploring party, some eighty years ago. This region promises to yield results of very great scientific value, and a thorough knowledge of it would go a long way to solve many of the problems connected with the Antarctic. The Weddell Sea is situated directly between the sphere of operations of the German expedition on the one hand, and the Swedish expedition on the other; so that the results of all three expeditions will be of advantage to each other on their return home. Details of cooperation or division of labour were carefully planned and arranged between the respective leaders of the Scottish, German and Swedish expeditions before the departure of the two latter. It is expected that the expedition will be absent more than a year at least, and possibly much longer if the necessary funds are forthcoming. The whole of the money subscribed towards the expedition has been given by Scotsmen only, and as the scientific staff and ship's officers and crew will also belong to the northern side of the Border, the whole project is a truly Scottish one.

M. C. GUTTON has described in the *Journal de Physique* for December some experiments tending to show that the wavelength of Hertzian oscillations is the same in water as in air. The corresponding property for castor oil has been previously proved by M. Blondlot; the present result is interesting, as in the case of water the imperfect conductivity gives rise to absorption of the oscillations.

A NEW method of determining the principal indices of refraction of a crystal by means of the critical angle has been investigated by M. Cornu, and the results are briefly detailed in the *Bulletin* of the French Physical Society, 172. The method is based on M. Cornu's geometric investigations of the total reflection at the surface of a crystal, and has been applied to calculate the indices of refraction in tartaric acid. In this substance the angle of conical refraction amounts to 4°, and interesting lantern experiments are described on the conical refraction of a crystal 23 mm. thick as well as on ordinary crystals of commercial tartaric acid immersed in clove oil.

THE design and construction of fly-wheels for slow-speed engines for electric lighting and traction purposes are discussed by Mr. A. Marshall Downie in the *Transactions* of the Scotch Institution of Engineers and Shipbuilders, xlv. 1. By projecting the indicator diagrams of the several cylinders of compound engines the author obtains curves representing the fluctuations in the combined crank efforts at different points of the revolution. From an examination of these fluctuations the author arrives at the conclusion that a good average value for the energy necessary to be stored in fly-wheels for electric lighting purposes is 2·9 foot-tons per electric horse-power, and in traction-plant 4 foot-tons.

FROM observations described by Prof Geitel in the *Physikalische Zeitschrift*, iii. 4, it appears that atmospheric air is itself capable of inducing radio-activity. When a mass of air remains shut up for a long time in a cellar or cave, Prof. Geitel finds that its electric conductivity increases to a maximum. There are three hypotheses possible, namely, that the exposed substances were themselves radio-active, that traces of radio-active substances were present in the neighbourhood, or that the air itself is the origin of the radio-activity. From experiments made with a kite at a considerable height above the ground and from other evidence, Prof. Geitel favours the view that the third is the most likely hypothesis.

DR. FOVEAU DE COURMELLES and M. G. Trouvé describe, in the *Bulletin* of the French Physical Society, certain new apparatus for the study of different light-rays of considerable intensity. These are based chiefly on the use of parabolic reflectors and other concentrators, and screens for filtering out the heat-waves or separating those of any required portion of the spectrum. The authors have applied their apparatus to the cure of lupus, tuberculosis, and other diseases at the Hospital of St. Louis in Paris, without producing any burning or blisters, the source of energy being an arc lamp of 10 amperes radiating for 10 minutes at 70 watts, or 8 amperes at 85 watts, while with Finsen's apparatus 75 to 80 amperes for 80 minutes are necessary.

THE arrangements for photochronographic observations in the physiological laboratory of Moscow University form the subject of a paper by Prof. L. Morokhowetz and Drs. A. Samojloff and A. Judin, published by the Imperial University Press. The room used for these observations is divided into four parts, one of which is described as a "monster camera," being a dark room in which the photographs can be exposed and watched during

the exposure. Among the apparatus used is a pendulum photochronograph, in which the pendulum carries a sensitive plate and is provided with a contrivance for releasing it at will and fixing it at the end of each half-oscillation. The papers are illustrated by photographs of the curves of different vowel sounds, taken in the laboratory.

THE problem of the perfectly irresistible body impinging on a perfectly impenetrable obstacle is scarcely more paradoxical than Poinsot's problem of a rigid body having two points fixed, when it is proposed to calculate the actual reactions and not merely the sum of the reactions along the line joining the points. The *Bulletin* of the Belgian Academy contains reports on a paper by M. Ferron, in which that author endeavours to overcome the indeterminateness of the problem by replacing the force Z at any point in the body by its components in the lines joining its point of application to the two fixed points. One of the referees of the paper, M. Ch. Lagrange, objects to the principle of transmission of force being applied in this case, but he does not hesitate to apply it in a paper of his own, in which he seeks to prove that each of the reactions is equal to $\frac{1}{2}$ Z.

A THEORY of progressive taxation, capable of being represented by simple mathematical formulæ, is discussed by Mr. G. Cassel in the *Economic Journal* for December. It is pointed out that the same results that are obtained by means of a graduated income-tax can equally well or better be effected by levying a tax at a constant rate per cent. and allowing suitable deductions to be exempted from taxation. Moreover, if a tax is to produce "equal sacrifices" the amount which should be exempted from taxation should be larger for large than for small incomes, as the cost of living consistent with efficiency increases with the amount of income to be earned. Mr. Cassel's proposal is based on the supposition of a "minimum of subsistence" representing the income exempt from taxation, and a "maximum of subsistence" representing the cost of living consistent with efficiency in earning an infinite income. The amount deducted for subsistence and the rate of taxation are then represented by formulæ of the form known to mathematicians as "homographic transformations."

IN the use of the wet and dry bulb thermometer for determining the pressure of aqueous vapour in air, considerable uncertainty is introduced by the presence of a constant which varies according to the conditions under which the thermometers are placed. The extremes are represented by August's formula, which supposes the air round the bulbs to be constantly changing, and Maxwell and Stefan's result, which is calculated on the hypothesis that the water on the bulb is evaporating and its vapour diffusing into an infinite mass of quiescent air. Signor G. Guglielmo, writing in the *Atti dei Lincei*, x. 9, now proposes to eliminate the arbitrary constant by the use of a *third* thermometer, the bulb of which is wetted by an aqueous solution the vapour tension of which differs considerably from that of pure water. In this way a further equation is obtained and the unknown constant is eliminated. Some preliminary experiments are quoted showing the efficacy of the method. The difficulties of applying it arise from the change in concentration of the solution caused by evaporation, and the consequent uncertainty as to its latent heat. But could not a second volatile liquid be substituted for the saline solution?

AT a recent meeting of the Meteorological Society of Mauritius, the secretary, Mr. T. F. Claxton, read an interesting paper on the objects for which that Society was established, in the year 1851. These were, chiefly:—To provide for regular observations in Mauritius and its Dependencies (Rodrigues, Seychelles, Diego Garcia, &c.), the establishment of a permanent observatory, and the collection and tabulation of observations taken in the Indian Ocean. Some of these objects have been successfully carried out, as shown by the *Transactions* of the Society and the annual reports of the Royal Alfred Observatory. The establishment of this observatory (in 1874) was perhaps the most important achievement of the Society; it is supported entirely from Government funds, and the director has always been the secretary of the Society. Every ship visiting the island is boarded and permission requested to extract observations for the construction of charts. Cyclone tracks of the Indian Ocean were published in 1891 and are of great use to navigators at the present time, and an important work has recently been commenced, viz. the tabulation into 5° squares of all the information collected from the log-books of vessels that have traversed the Indian Ocean since 1854, with the view of constructing a meteorological atlas of the south Indian Ocean; this will doubtless be of much practical use to sailors. Unfortunately, there has been a steady decrease in the number of vessels trading with Mauritius, from 787 in the year 1878 to 283 in 1900, so that the construction of daily synoptic weather charts begun by Dr. Meldrum about 1860 has had to be discontinued, except during cyclone weather.

THE Imperial Department of Agriculture for the West Indies has issued a second, and revised, edition of Mr. Maxwell-Lefroy's pamphlet on "The General Treatment of Insect Pests." Another of the pamphlet series, No. 11, "Hints for School Gardens," by the technical assistant, Mr. William G. Freeman, has just been published. It deals, in simple language, with the most elementary principles of agriculture, taking box and pot cultivation as the starting point for school work, and going on to gardening—growing vegetables and flowers and experimenting with manures. Mr. Freeman has written a useful handbook, which should be studied by teachers with Mr. Watts's "Nature Teaching" recently noticed here.

IN his annual report on the Antigua Botanic Station, Mr. W. N. Sands, the curator, gives a complete summary of the work for the year ending March 31, 1901. The most interesting feature of the report is a detailed account of an experiment designed to ascertain what a small plot of land about the size of a peasant garden or negro ground would produce in provisions, if properly managed and arranged. The usual method adopted by the peasantry is to grow one or two crops only, and for which they have to wait about five months for a return, which is often poor, and then selling out for a few shillings, often pence. At the Botanic Station a patch 1/10 acre in extent, and overgrown with grass, was taken in hand, and, having been duly cleared, forked and manured, nineteen varieties of vegetables were sown or planted at various periods. In due time such of them as matured were reaped, and sold locally. The sum realised for the produce of the patch was 2*l*. 15*s*., the expenditure having been 1*l*. 15*s*. 3*d*. Of the latter sum, however, 1*l*. 4*s*. 8*d*. was expended on labour, which would not come out of the peasant's pocket, as he would attend to his garden in his spare time. By the exercise of a little intelligence, therefore, a peasant could make a profit of 2*l*. 4*s*. 5*d*. out of 1/10 acre of land in nine months.

THE most important paper in the *Transactions* of the Hull Scientific and Field Naturalists' Club for 1901 is one by Messrs. F. W. Mills and R. H. Philip on the diatoms of the Hull neighbourhood. It is illustrated by no less than sixteen plates, drawn by the first-named author.

THE October issue of the *Bulletin* of the Cracow Academy of Sciences contains an important article, by M. Godlewski, on the development of muscular tissue in mammals; and a second, by M. Przesmycki, on certain protozoans parasitic in rotifers. Both are elaborately illustrated.

M. ARMAND GAUTIER contributes to the *Revue Générale des Sciences* of December 15, 1901, an article entitled "Les Mécanismes moléculaires de la Variation des Races et des Espèces," taking as his text the experiments in hybridisation made of late years with the French and American species of vine.

MANY animals have popular names which have been derived from their cries. Prof. T. D A. Cockerell writes to suggest that this is also the case with the donkey, the "don" representing the inspiratory and "key" the expiratory sound. Most dictionaries describe the word, which is of comparatively recent origin, as signifying a little dun animal, from dun and the diminutive term—key, but the grounds upon which this derivation is based are not easy to find.

TO the *Proceedings* of the Washington Academy of Sciences (vol. iii. pp. 577–600) Dr. C. H. Merriam contributes a paper on the various local forms of the puma. It has long been recognised by naturalists that an animal with such an extensive range must be divisible into a considerable number of geographical races; but Dr. Merriam goes further than this, and considers that several of these ought to rank as species. If such a course were generally adopted it would be advisable to make the puma the type of a genus. Dr. Merriam remarks that these animals are very subject to cleft palate.

WE have received reprints of a series of articles from the November issue of the *Journal* of the Quekett Microscopical Club. In one, Mr. W. Wesche describes a new male rotifer from Hampstead Heath, while Mr. C. F. Rousselet treats of a new species of the same group in a second. In a third, Mr. D. J. Scourfield has notes on the manner in which the fresh-water polyp hydra suspends itself from the surface-film of water. In a note on "red rain dust" from Australia, Mr. G. H. Karop shows that, in addition to mineral matter, the substance in question contains a certain number of diatoms, and a percentage of what appear to be sponge-spicules.

WE have received the first number of a new journal, *The Emu*, published at Melbourne, which is to be the organ of the Australasian Ornithologists' Union. In the introductory notice the editor discusses the question whether the name of the bird from which the journal takes its title should be spelt "emu" or "emeu." We are told that the native pronunciation is *emyoo*; and if this be so, according to accepted ideas of transliteration *emeu* makes a nearer approximation to the original than *emu*, which would now be pronounced *emoo*. The number before us contains some interesting articles and a couple of excellent photographs of breeding colonies of gannets and frigate-birds. The new venture ought to have a successful future.

A SHORT time ago we noticed a communication by Prof. T. H. Morgan on the regeneration of limbs and other parts of the body in animals. The same investigator contributes to the December issue of the *American Naturalist* an article on regeneration in the egg, embryo and adult. Within the last few years it has been ascertained that portions of an embryo, or even of an unsegmented egg, have the power of producing a new organism; but it has not been determined whether regeneration of parts of an adult organism and of pieces of an egg are similar or identical processes. The author answers the question in the affirmative, but denies that there is any analogy between this process and the natural reparation of a broken crystal. Nevertheless, he connects this recuperative process in animals with a kind of organic "polarity."

THE Christmas number of the *Stock-keeper* is largely devoted to illustrations and descriptions of famous specimens of the more popular breeds of domesticated dogs. The editor, it appears, offered a number of prizes for the best photographs of well-bred dogs by amateurs, and the successful pictures, together with many others, have been reproduced as photogravures in the present issue. Attention is called in an article on the results of the competition to the importance of preserving photographs of the modern breeds of dogs, and regret is expressed that we possess no such records of their predecessors. It may be added that it would be of the highest importance if arrangements could be made for taking photographs of dogs (and other domesticated animals) from above as well as from in front and from the sides.

IN their fifteenth annual report the Liverpool Marine Biological Committee refer with satisfaction to the arrangement concluded with the Government of the Isle of Man whereby they will in future enjoy much larger laboratory accommodation, and, jointly with a committee of the Tynwald Court, be responsible for the conduct of a large aquarium and fish-hatchery. A detailed statement as to how this important change in the position of the committee has been brought about is given, while its probable effects on their work are also mentioned. The greatness of the change may be realised when we state that it involves the moving of the present biological station to a larger and more convenient site on the other side of the bay. The work accomplished during the past year appears to have been large and of a satisfactory nature. The report contains an excellent popular guide to the Port Erin Aquarium, illustrated by figures of a large number of its denizens. Prof. Herdman is to be congratulated on the continued progress of the institutions the interest of which he has so much at heart.

A NOTICE of the collections recently bequeathed by the late Mr. Philip Crowley to the natural history branch of the British Museum appeared a few days ago in *The Times*. A very important portion of the bequest is the collection of eggs, from which 15,200 specimens have been added to the series previously possessed by the Museum. Among the gems in the Crowley cabinet are an egg of the great auk and one of the extinct pied Labrador duck. Both these specimens were acquired by Mr. Crowley from Canon Tristram. The great auk's egg is one of the last "batch" despatched, in 1844, from Iceland to Denmark. The two specimens in the Museum previous to this addition were both cracked and in otherwise poor condition. An interesting item in the collection is the number of clutches of eggs of various species of birds with a cuckoo's egg among them. The Crowley collection has added about 15 per cent. to the species of birds represented by their eggs in the Museum, the increase being especially marked in Australian forms, in which the national collection was previously weak. In addition to eggs, the Museum also acquired a large series of invertebrates, especially butterflies, from the Crowley collection. The article concludes with a reference to the valuable series of specimens from the Uganda district recently presented to the Museum by Sir Harry Johnston. Apart from the okapi and five-horned giraffe, this collection includes a valuable series of fishes from Lakes Victoria and Barengo—the first ever obtained from these waters.

A CATALOGUE of the Mediterranean algæ is commenced by Prof. Francesco Ardissone in the Lombardy *Rendiconti*, xxxiv. 17. The first part deals with Rhodophyceæ, and the author has decided, for stated reasons, to adopt Agardh's classification.

THREE additional volumes of the Yale University Bicentennial Publications have been received. Two contain studies from the chemical laboratory of the Sheffield Technical School, edited by Prof. H. L. Wells, and the third is a text-book on vector analysis, for the use of students of mathematics and

physics, founded upon the lectures of Prof. J. Willard Gibbs by Dr. E. B. Wilson. The volumes can be obtained in London from Mr. Edward Arnold.

THE kinematograph is now so frequently employed to reproduce the characteristics of moving objects and scenes that everyone is familiar with its pictures. But twenty years ago, when Mr. Muybridge projected before an audience at the Royal Institution a series of moving pictures illustrating animal locomotion, the results were regarded as veritable photographic triumphs. Since then photography has been utilised in the analysis of motions of many animate and inanimate objects, but Mr. Muybridge's collection of pictures is still the standard work on the various changes which take place in the disposition of the limbs and body of common animals during motion. A cheap edition (price 20*s.*) of the plates illustrating "The Human Figure in Motion" has been published by Messrs. Chapman and Hall, and will doubtless be appreciated by artists and students of anatomy who are unable to study the elaborate work in which the pictures originally appeared.

THE "Annuaire" of the French Bureau des Longitudes is a wonderful repertory of statistical and other information requiring frequent revision if it is to represent existing conditions of knowledge. In the volume for 1902, received a few days ago, we notice that all the dates are expressed in mean civil time, reckoned continuously from 0 hour to 24 hours, and beginning at midnight. The catalogue of minor planets has been brought up to October 2, 1901. M. E. Levasseur brings the statistics of the population of Europe up to the end of October last; and the magnetic elements of the chief places in France are given for the epoch January 1, 1902. As in previous years, there are articles on subjects of wide scientific interest. To the present "Annuaire" M. H. Poincaré contributes an article on telegraphy without intervening wires; M. A. Cornu writes on polyphase currents; M. E. Guyou on the application of the decimal division of the quadrant of a circle to navigation; and M. J. Janssen on the establishment and work of the observatory on the summit of Mont Blanc.

THE as yet unanswered question concerning the source and mode of production of the free electricities, which appear on the separation of two heterogeneous bodies which have been in contact, is the subject of an interesting paper by O. Knoblauch in the last number of the *Zeitschrift für physikalische Chemie.* Seventy-five different substances of various characters were brought into contact with plates of platinum, paraffin, sulphur, and glass, and the positive or negative character of the charge received by the plate on separation was in each case determined. By the assumption of an absorbed film of water on the surfaces of these different bodies, the author finds it possible by application of well-known principles of the ionic theory to account for the character of the charge received by the one substance after it has been in contact with a second.

THE additions to the Zoological Society's Gardens during the past fortnight include a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Captain B. Head; ten Crab-eating Raccoons (*Didelphys cancrivorus*) from South America, a Gangetic Trionyx (*Trionyx gangeticus*) from the Ganges, fifteen Tigrine Frogs (*Rana tigrina*) from India, deposited; a Crimson-breasted Barbet (*Xantholoema haematocephalus*) from India, a Variegated Sheldrake (*Tadorna variegata*) from New Zealand, purchased; a Campbell's Monkey (*Cercopithecus campbelli*) from West Africa, presented by Mr. F. R. Paxman; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Dr. Gray; a Bonnet Monkey (*Macacus sinicus*) from India, presented by Mr. D. Justice.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JANUARY.

Jan. 3. Epoch of January meteoric shower (radiant 230° + 53°).
5. 11h. 28m. Minimum of Algol (β Persei).
8. 8h. 17m. Minimum of Algol (β Persei).
9. 10h. Saturn in conjunction with the sun.
9. 15h. Venus at greatest brilliancy.
11. 5h. 5m. Minimum of Algol (β Persei).
12. 4h. 17m. to 5h. 27m. Moon occults c' Capricorni (mag. 5·2).
12. 18h. Venus in conjunction with moon. Venus 3° 8′ S.
13. 6h. 23m. to 7h. 1m. Moon occults κ Aquarii (mag. 5·5).
15. Venus. Illuminated portion of disc = 0·218, Mars = 0·990.
15. 11h. Jupiter in conjunction with sun.
21. 8h. 15m. to 8h. 39m. Moon occults 71 Orionis (mag. 5·1).
22. 16h. 56m. to 17h. 28m. Moon occults 68 Geminorum (mag. 5·0).
24. 6h. 7m. to 7h. 1m. Moon occults κ Cancri (mag. 5.0).
24. 17h. 23m. to 18h. 0m. Moon occults ω Leonis (mag. 5·6).
26. 18h. 38m. to 19h. 30m. Moon occults p^5 Leonis (mag. 5·5).
27. 21h. Juno in conjunction with moon. Juno 1° 11′ N.
28. 9h. 59m. Minimum of Algol (β Persei).
31. 6h. 48m. Minimum of Algol (β Persei).

STARS NEAR NOVA PERSEI.—Prof. Ceraski reports in the *Astronomische Nachrichten* (Bd. 157, No. 3755) that on a photograph obtained on the night of 1899 January 30 there is a small star very near the position at present occupied by the Nova. Visual observations with a 15-inch telescope now fail to locate the star, and he asks astronomers with powerful instruments at their disposal to examine this region. The coordinates with respect to the Nova Persei are:—

$$\text{R.A.} = \alpha \text{ Nova} + 0^s{\cdot}31.$$
$$\text{Decl.} = \delta \text{ Nova} - 7''.$$

As estimated from the photograph, the star would be of about the 12th magnitude.

MAGNETIC OBSERVATIONS DURING TOTAL SOLAR ECLIPSE.—In the *Journal of Terrestrial Magnetism and Atmospheric Electricity* (vol. vi. pp. 123–143) reports are presented showing the details of observations of the magnetic declination, horizontal and vertical forces during the total solar eclipse of May 17–18, 1901. The stations employed for the determinations given in this issue were at Pola, Austria; Val Joyeux, France; Groningen University, Holland; De Bilt Observatory, near Utrecht; Flushing, Holland. Further reports will be published later, and the whole discussed with the object of investigating the perturbations due to extra-terrestrial causes.

THE TOTAL SOLAR ECLIPSE, MAY 18, 1901.—In *Popular Astronomy* for December, 1901, Prof. E. E. Barnard gives a long description of the preparation, equipment and preliminary experiments undertaken in connection with the last eclipse, and although the weather conditions prevented any positive results being obtained, the record of his methods of dealing with apparatus on such great scale—the plates used were 40 × 40 and 30 × 30 inches—will be of considerable interest and value to workers on future occasions.

NATAL OBSERVATORY REPORT FOR 1900.—The report recently issued by the Government Astronomer of Natal contains as a supplement the details of the observations at the various meteorological stations throughout the colony during the year 1900, with summaries. The returns of several stations are unavoidably incomplete in consequence of the unsettled state of the country.

The instruments, with the exception of the 8-inch Grubb equatorial refractor, are in good order. This instrument will, it is hoped, be shortly dismounted and thoroughly overhauled.

The system of time signals is now established over the colony and is working satisfactorily.

PRIZE AWARDS OF THE PARIS ACADEMY OF SCIENCES.

AT the annual meeting of the Academy of Sciences, held on December 16, 1901, the presidential address was given by M. Fouqué and the following prize awards were announced:—

Geometry.—M. Léonce Laugel is awarded the Francœur prize and M. Émile Borel the Poncelet prize.

Mechanics.—The extraordinary prize of six thousand francs is divided between M. Tissot for his work relating to the utilisation of wireless telegraphy in the Navy, and M. Marbec for his calculations on the strength of tubular boilers; M. Aimé Witz receives the Montyon prize, and M. Boulvin the Plumey prize for his applications of the entropy diagram to the steam engine. The Fourneyron prize, the subject proposed for which was the theoretical or experimental study of steam turbines, is not awarded.

Astronomy.—The Lalande prize to M. Thome, and the Valz prize to M. Charles André for his treatise on stellar astronomy.

Physics.—The La Caze prize is awarded to M. Curie for his work on radium and on piezo-electricity of crystals, the Gaston Planté prize to M. G. Boucherot, the Kastner-Boursalt prize to MM. H. Gall and de Montlaur for their electrochemical work.

Statistics.—The Montyon prize for statistics is given to M. G. Baudran for his work on tuberculosis in the Department of the Oise, a very honourable mention being accorded to the memoir of MM. Delobel, Lebrun and Cozette on the statistics of contagious diseases of animals in France, and to M. Lowenthal.

Chemistry.—The Jecker prize is divided between MM. Moureu, Simon and Léo Vignon, MM. Wyrouboff and Verneuil receiving the La Caze prize for their researches on the rare metals.

Mineralogy and Geology.—The Delesse prize is awarded to M. Gaston Vasseur for his work on the classification of the Tertiary strata in the west and south-west of France.

Physical Geography.—The Gay prize is divided between MM. Franchet and Saint-Yves.

Botany.—MM. Matruchot and Molliard receive the Bordin prize for their work on the influence of the external conditions on the protoplasm and nucleus in plants, M. Karl E. Hirn the Desmazières prize, M. Mazé the Montagne prize for his researches on the mechanism of the fixation of nitrogen by the Leguminosæ, M. Ferdinand Debray the de la Fons-Mélicocq prize, and M. N. Patouillard the Thore prize for his taxonomic essay on the families and genera of the Hymenomycetes.

Anatomy and Zoology.—The grand prize of the Physical Sciences is awarded to M. Maupas for his two memoirs on the biology and the origin of the sexual elements in Nematods, and the Savigny prize to MM. Jules Bonnier and Ch. Pérez for their exploration of the Red Sea and the Persian Gulf.

Medicine and Surgery.—The Montyon prize is divided between MM. Buffard and Schneider, Lignières, and Claude and Balthazard, the Barbier prize between MM. Moreigne, Tissier, and Goyon, the Breant prize in equal parts between MM. Jules Courmont and V. Montagard, Weil, and Levaditi; M. René le Fur receives the Godard prize, M. Gley the Mége prize, whilst the Bellion prize is divided between MM. Landouzy and G. Brouardel, and M. Sauton, very honourable mentions being accorded to M. Razou and M. Pégurier. The Lallemand prize is divided between MM. Catois, J. C. Roux and J. Lépine, MM. F. Bernheim and A. Comte receiving very honourable mention. M. Catrin receives the Baron Larrey prize for his work on mental alienation in the Army, an honourable mention being accorded to MM. Tostivint and Remlinger for their memoir on the comparative pathology of the European and Arabian races.

Physiology.—The Montyon prize for experimental physiology is awarded to M. Marcel Mirande, M. Bonniot being accorded an honourable mention, the Pourat prize to M. Tissot for his researches on the cooling due to muscular contraction, the La Caze prize to M. Charpentier, the Philipeaux prize being divided between MM. L. Camus and M. Moussu.

General Prizes.—The Lavoisier medal is awarded to M. Emil Fischer, professor of chemistry at the University of Berlin, correspondant of the Academy, for the whole of his works and in particular for those relating to the syntheses of the sugars. The Montyon prize (unhealthy trades) is divided between MM. Albert Dormoy and L. Vaillard, M. Halphen receiving an encouragement. M. Baubigny receives the Wilde prize for his work on atomic weights, MM. Fosse and Grignard the Cahours prize (in equal parts), P. Stanislas Chevalier the Tchihatchef prize for meteorological and astronomical studies in China, M. Gabriel Lippmann the Jean Reynaud prize, M. F. Foureau the Leconte prize for his scientific explorations in southern Algeria, M. Foureau the Janssen gold medal, and MM. N. Villatte, E. Verlet-Hanus and A. P. de Chambrun silver gilt medals for their work in the Sahara, M. Gabriel Kœnigs the Petit D'Ormoy prize for his researches in geometry and mechanics, M. Bouvier the Petit D'Ormoy prize (natural sciences), M. Guichard the Saintour prize, M. A. Ponsot the Gegner prize, M. Frémont the Trémont prize.

The Baron de Joest prize is divided between MM. Verschaffel and Saint-Blancat for their astronomical work, the prize founded by Mme. la Marquise de Laplace being given to M. Japiot, and that founded by M. Félix Rivot to MM. Pellarin, Ott, Japiot and Guillaume.

ELECTRIC WAVES.

THE annual meeting of the German Association of Men of Science and Physicians was held last autumn in Hamburg. It is twenty-five years since the Association last met in the birthplace of Heinrich Hertz, who was then a young man of nineteen, not yet entered upon the active period of his life, which ended by his death in 1894, and which, though so short, was yet so great and full of usefulness. It fell, therefore, to the lot of Prof. Ernst Lecher to deliver this address[1] in memory of Hertz and to review the further development, which has taken place since his death, of his greatest work, the experimental proof of the existence of electric waves.

It is, indeed, a long chain of events, as Hertz himself expressed it, to which the discovery of electric waves belongs, one event linking itself into another, the whole forming perhaps the most noble and convincing proof that our modern methods of scientific thought and research are true and exact. Prof. Lecher gives an interesting sketch of this in the pamphlet before us. The first link in the chain was forged by Faraday. Until his time the scientific world was dominated by the old Newtonian ideas of force acting at a distance, an idea which seems to us now, on close examination, to be manifestly absurd. It required, however, the genius of Faraday to break loose from this line of thought and to perceive that a medium is necessary in order that one body may exert a force upon another; and to the eye of Faraday the whole of space became filled with lines and tubes of force, real changes of condition in the intervening media, which, although invisible, were as clear to him as the objects acted upon themselves. The way was thus paved for Maxwell, who collected these ideas in his really magic formulæ of the electrodynamical theory of light. According to Maxwell there are electric currents in insulators, these being of the nature of displacement currents. Although these currents are of very short duration, yet they must have like magnetic and inductive effects to the ordinary currents in a conductor. If, now, a displacement current vibrates backwards and forwards, then in a neighbouring insulator displacement currents will be induced, and so forth; a transversal wave-motion is thus propagated until it is absorbed by induction in a conductor and transformed into heat. On calculating the velocity of this wave propagation it was found that two quantities appeared in the result—the dielectric coefficient and the permeability. The square of the velocity is equal to the reciprocal value of the product of these two values. It was found, however, that whole powers of this value were always appearing in different branches of the theory of electricity, and, most extraordinarily to say, the value was always found to be equal to the velocity of light. Maxwell, therefore, came to the theoretical conclusion in 1865 that an electromagnetic wave must travel in an insulator, *e.g.* in air or vacuum, with the velocity of light. But not only the velocity, concluded Maxwell, should be the same, but also the geometrical and other properties must be equal; a ray of light was therefore a series of electric waves, light was electricity. These ideas, immediately after their enunciation by Maxwell, did not meet with any great acceptance, and an experimental proof of their accuracy was looked upon as being altogether out of the question. This feeling was even shared by Hertz himself, for in his description of his classical experiment where, by means of a

[1] Ueber die Entdeckung der elektrischen Wellen durch H. Hertz und die weitere Entwicklung dieses Gebietes. (Leipzig: Johann Ambrosius Barth.

spark gap in a loop of wire, he showed the sparks induced by the electric waves at a distance of ten metres from the transmitter, he said: "It appears impossible, nearly nonsensical, that these sparks should be visible, but in a perfectly dark room they *are* visible."

Since the death of Hertz it can hardly be said that another link in the chain of development has been forged. Our knowledge and study of electric waves have spread and expanded enormously, and the practical utilisation of the same is seen in the modern wireless telegraphy. The possibility, as Marconi has shown, of already sending messages without the use of wires for a distance of 300 kilometres is the direct result of the labours of Hertz. From a theoretical standpoint the work of the many investigators of the last few years has simply increased the burden of proof that the fundamental ideas of the electrodynamical theory are correct. Many points, however, yet remain to be cleared up. In the domain of the ether itself very few difficulties have been encountered. Very different has been the case when the ether pure and simple has been left and the theory and ideas extended to ordinary bodies and materials. Chief among these difficulties must be mentioned the phenomena of anomalous absorption and dispersion, and the relative interaction of mass and ether is to-day one of the most perplexing and yet enticing fields of scientific work. Perhaps here we are, though it is not mentioned in the pamphlet, just commencing the forging of yet an entirely new link, which will be seen in the full development of the corpuscle and electron theories, and the explanation of the many at present very strange phenomena included under these names. Besides being a very interesting address, this booklet would be very useful in serving as an index to the many investigations which have been made and published in this branch of science.

C. C. G.

THE CIVILISATIONS OF HALLSTATT AND LA TENE.[1]

THE publications of the Prehistoric Commission of the Imperial Academy of Science in Vienna, in their present form, date from the year 1887, when it was resolved to discontinue the practice of publishing their reports as integral parts of the *Transactions* of the Academy. The primary object of this commission was to prosecute palæo-ethnographical investigations throughout the Austrian dominions, taking special care that the necessary excavations would be conducted in a thoroughly scientific manner. Since 1887 five parts, in all 363 pages, in quarto, with plates and numerous illustrations in the text, have been issued, giving on an average only twenty-eight pages per annum—a rate of progress which, *primâ facie*, does not suggest that such researches are advancing with rapid strides in that part of Europe. Looking, however, at the contents of the various papers and reports, which range over the whole field of prehistoric archæology, I am constrained to say that, in forming a fair estimate of the archæological value of the labours of the commissioners, we must be guided by quality and not by quantity.
